THE RIGHT TO A NEGATIVE.—In the Swansea County Court, on Friday last, the 21st instant, a case possessing interest to photographers was tried before Judge B. T. Williams, Q.C. It was a claim with respect to certain photographs of the Naval Volunteers.—Mr. Andrews, photographer, Wind-street, sued Mr. Robert Capper, superintendent of the Swansea Harbour, for £5 8s. 6d. Mr. Monger appeared for the plaintiff, and Mr. Glascodine for the defendant. The claim arose in connection with certain photographs of H.M.S. Dwarf, which was in Swansea in September last. Defendant commissioned the plaintiff to execute views of the vessel on her arrival in and departure from the port, together with groups of officers and men on board—an order which the plaintiff duly carried out. He delivered several copies to Mr. Capper, and supplied copies to others. The amount charged was £10 11s. 6d., £5 8s. 6d. of which was for "photographing" the vessel and groups, and £5 3s. for the copies supplied. Mr. Capper paid for the copies supplied, and offered to pay the £5 8s. 6d. if Mr. Andrews handed over the negatives, but the plaintiff claimed that the negatives continued his property.—For the defence, it was urged by Mr. Glascodine, that as the plaintiff claimed to charge for executing the negatives they belonged to the defendant, who gave the order, and was charged for making them.—The Judge: If you order a photograph, unless you make special terms for the purchase of a negative the photographer is not entitled to give it up.—Mr. Glascodine said if he asked a man to make something for him, and he afterwards asked for copies and paip for them, they were his. If a photographer charged him for taking a negative, did it not belong to him?—The Judge: No; it is part of the instruments used in the business. It is what a photographer uses in his business to make photographs. Why should he part with the instruments of his trade? A negative may be a secret in his trade, and he does not part with it unless there is a contract to that effect.—Mr. Glascodine: Suppose I ask a man to make me an engine for £500, and suppose he charges me £250 for the patterns, do the patterns belong to me or do they not? If he charges me for them they are mine. If he does not charge me for them then, of course, they are not mine.—The Judge: But here he does not charge for the negative. He charges for his work and for copies, and he makes an estimate accordingly. You want photographs for your friends. It does not matter to you how he makes or produces them. There might be other means to produce what you want; therefore what has this to do with you. He charges you for the expense in producing what you want. As I said before, he estimates the cost of producing, but does not sell the material used in the production. He wants it for other purposes. If you like I will give you leave to appeal.—Mr. Glascodine: If so that will be sufficient. Perhaps you will be good enough to note what I said about the making of an engine and the patterns.—His Honour: Quite so; I find as a fact that the photographer never sold the negatives to the defendant, and I give judgment for the amount claimed with costs and advocate's fees. I give Mr. Glascodine leave to appeal. I think, however, it will be useless to appeal.

Infringement of Copyright.—At the Mansion House Justice-room, on Friday last, the 21st instant, William Smith, a wholesale photograph dealer, in Vine-street, Minories, was summoned for an infringment of the Copyright Act in selling pirated copies of a photograph of Miss Mary Anderson. There were nine more summonses in respect of other photographs. Mr. Foote was counsel for the prosecution; Mr. Tickell for the defence. Evidence was given that the copyright of the photograph in question of Miss Anderson was vested in Mr. Henry Van der Weyde, of 182, Regent-street, and it was alleged that the pirated copies had been sold by the defendant to hawkers at the rate of six shilliegs per gross. Among other places at which they were sold was at the recent World's Fair at the Agricultural Hall, and it was asserted that the defendant when selling them advised that they should not be publicly exposed. Mr. Tickell submitted that the defendant had no guilty knowledge that the photograph was a piracy, and stated that he had sold none since his attention had been drawn to the matter. The Lord Mayor said the defendant had been before the Court previously in discreditable circumstances connected with the sale of photographs, and he thought the case was proved. The defendant then pleaded "Guilty" on the other nine charges, the circumstances being said to be the same. The Lord Mayor fined the defendant £10 in each of two cases and £3 3s. costs in each, and respited judgment in the remainder of the charges. The defendant paid the fine.——On Saturday last, the 22nd, the same defendant, William Smith, was also prosecuted at the Worship-street Police Court, by Messrs. Poulten and Son, of Lee, Kent, for selling pirated photographs.

Supreme Court of Judicature—Queen's Bench Division.—On Saturday last, the 22nd instant, before Mr. Justice Denman and Mr. Justice Manisty, the case of Martinucci *versus* Martinucci was tried. This action arose out of the following circumstances:—Lombardi, the elder brother of the defendant, came to England, and subsequently carried on the business of a photographer at Brighton and in London. He was followed by the defendant Eugenio; and they became connected together in business. The elder brother made various advances to the younger, who, on the 26th February, 1880, gave him an I O U for £642 2s. 1d. On the 28th May following £200 was paid off this debt, and the widow of Lombardi now sued to recover the balance. The case for the defence was that on the 10th July, 1880, his brother brought the I O U, gave it up to him, saying "Let all the past be buried, and begin again," and it was arranged that the defendant should from that time manage the London house. Lombardi died in August following, and in January, 1881, the defendant was applied to for the balance due by him, and he then produced the I O U and gave that account of how it had been delivered up to him. It bore upon it, in the handwriting of Lombardi, "Received on account, £200, 28th May, 1880," and it was suggested by the plaintiff that the defendant might have improperly possessed himself of the document. The trial took place before Mr. Justice Smith, when the verdict was for the defendant, but the present application was for a new trial, upon the ground that the verdict was against the weight of evidence.—Mr. Willis, Q.C., and Mr. Glyn were for the plaintiff; and Mr. Lockwood, Q.C., and Mr. Sharp for the defendant.—Mr. Justice Denman, in giving judgment, went elaborately through the facts of the case, and said that the question raised was one which was eminently with the jury. The Judge who tried the case said that it was one of some doubt and difficulty, and there was a great deal to be said in favour of one view and of the other. The whole thing was fully discussed before the jury, and he was not dissatisfied with the verdict. The Court, on their part, could not say that it was an unreasonable verdict, and therefore they could not interfere.—Motion dismissed with costs.

RECREATION IN ART.*

Photography, of all the arts, is one of the most *practicable* as a source of recreation in the largest and widest sense. It gives opportunity for the employment of every faculty. Brain and hand, muscle and nerve must equally come into play. But not only these, which are but the generalities of our possessions - there must come into full occupation taste, judgment, observation, a quick sense of harmony, of space and time, of cause and effect, and, above all, a deep knowledge and love of nature. To him who possesses these qualities not only will photography be an *available* art, but one in which he will find endless and ever-widening recreation.

On the other hand, to him who is content to learn merely the technicalities of the art, going no further than the acquisition of such knowledge as will enable him to secure a *plate* and a subsequent print therefrom, the word "recreation" does not characterise his work in any great degree, and much less the term "artistic." There is always the question of degree in every subject, and it would be folly not to admit that occupation in its humblest form is not rest and recreation to some. To that extent the manipulative details involved in the taking of a photograph may be called "recreation." But it is not in that sense that I would speak of photography as a recreation. It is only recreation in a true sense when it draws out slumbering talents, unused faculties, discarded aims, or faded aspirations.

To the man who has been engrossed all his life in the drudgery of business, occupying a certain round of faculties, day by day, in unvarying monotony but exhausting pertinacity, it is evident that by far the larger and, it may be, the better part of his being is entirely unused. These, by their inactivity, are liable to languor and die; and, as a matter of fact, I believe that most people suffer the loss, through time, of many powers which were in their youth latent and waiting to be developed, but which, in the exigencies of the calling which they had to pursue, were allowed to become fallow, and ultimately dropped out of sight.

There are village Hampdens occurring every day in the crushing system of *specialities* demanded by the nature of our civilisation, and it is only by an accident, by sickness or some such cause, that we discover in a full-fledged medical man, for instance, such a consummate artist and etcher as Symon Haden. Artists do not lie hidden in *every* doctor any more than wisdom lurks under every gown; but it may be safely affirmed that there are possibilities of art-culture latent in every one, be his daily calling what it may, and no better instruments exist for calling these possibilities into play than the camera and the sensitive plate.

With these a man may discover a whole continent *in* himself of powers and capacities that were known neither *to* himself nor his friends. Many in this Society, I have no doubt, could verify that assertion in their own experiences. By the use of the camera they have come to realise what beauty and grandeur *is* in nature, and their great ambition as well as delight is to be able to secure transcripts of these as momentos of things their souls now love. Before they knew it *form* had no poetry, no enchantment for them. Outlines and space were but elements of objects that were so common, and of "the nature of things," as to be unworthy of observation. Now the camera has shown to them that all things, the commonest and the meanest, have a beauty, a charm, and a character that is not only worthy of passing observation, but of transcription and preservation. Need I refer, in illustration of this, to the last popular entertainment of the Society. On that occasion (as well as on many former ones) there were representations of objects the charm of which lay entirely in the delineation of form. This was particularly the case in groups of cattle and of birds. Few people but would confess to a liking of either horses or swans from their boyhood up—that liking resting, however, chiefly, if not entirely, on the intelligence and gentleness of the creatures rather than on their æsthetic qualities. Those, on the other hand, who "took" those groups I have referred to, took them because they had come to appreciate and love *form*. I say nothing about the *sentiment* that may exist in a picture of cattle listlessly standing knee-deep in a stream, or of sheep browsing on a quiet hill-side. Their motions are not the least of the aspects that strike the mental excitation. But where you find an amateur "catching" horses standing heads and tails in a stubble field, with no picturesque accessories to enhance or even to form a picture, be sure that he has his mind bent on securing those graceful lines, those fascinating contours that have ever made the horse a favourite with artists and lovers of nature. He has caught the infection of beauty, and is on the way to understand its principles without the tedious drudgery of studying definition, explanations, and all the paraphernalia of science and literature. Already he has mastered, perhaps, more than Hogarth could impart to him in his interesting *Essay on Beauty*, with his investigations into the secrets of the ancient masters, and his laborious conclusion that it consisted after all in the use of the curved or spiral line—the line of beauty and of grace.

But, besides *form*, which is the *chief* object of the camera to secure, there is the indication of air, space and distance, tone, colour, and definition to be obtained; and these must first be seen and appreciated before they will find their proper representation in the finished picture. This also, it is gratifying to say, was well illustrated in the collection shown at the last meeting. Some sea-pieces, with yachts in full sail and steamers *en route*, showed considerable feeling of tone and air effect, both sky and sea being in many cases harmonised remarkably; so soft and at the same time so firm were the relative tone-values that no difficulty was experienced in distinguishing degrees of distance and local effects. Those who set themselves to take "pictures from nature" by the camera are thus bringing themselves into contact with the very spirit of nature, from which contact, with its deeper knowledge and keener insight, there arises love and admiration—a desire ever to be with it, to share its bounties; and *this* is the essence of real æsthetic recreation.

J. Hutchison Simpson.

SPECIFICATION PUBLISHED DURING THE PAST WEEK.

MANUFACTURE OF PLIABLE PLATES AND SURFACES AS A SUBSTITUTE FOR GLASS FOR PHOTOGRAPHIC PURPOSES, &c.

THE following is the specification of JOSEPH JULIUS SACHS, London, a communication to him from Messieurs Fickeissen and Becker, Villingen, Baden, Germany.

This invention relates to the manufacture of pliable plates and surfaces for various purposes. These plates or surfaces can be prepared from paper, cloth, or other suitable fabrics or materials, but by preference from white paper which contains very little size and does not possess much grain. This paper is first extended on a frame or other arrangement, according to the size of the plate or surface which is desired. After it is dry, the surface is covered in any convenient manner with a fine varnish or composition, such as copal varnish, for the purpose of rendering the fabric transparent; it is then dried, and after it is quite dry the surface is rendered smooth by the application of powdered pumice stone or other suitable material, or it may be smoothed by suitable machinery. This process of smoothing may be repeated, if necessary, two or three times until the surface or plate is smooth or transparent. The surface so prepared is then covered on one or both sides with a solution of gelatine, isinglass, or other substance possessing similar properties, and allowed to dry. The surface so prepared may, if desired, be further treated with a preparation of ox-gall from which the fatty matter has been extracted by acetate of alumina or similarly acting agents which will precipitate the fat of the gall, the resulting preparation being then passed through a filter, whereby a clear solution will be obtained with which the plate or surface may be covered so as to secure the safe reception of the emulsion for photographic or other use. Instead of ox-gall any similarly acting substance or material may be used.

The plates or sheets prepared as above may be used with great advantage in reproducing photographs from nature in lines or stipples for calico and other printing, as the stipples or lines can be printed first on the material before it is made transparent. Any photographic design or drawing can be put on the transparent surface in the usual way, and by using the said film as a negative or positive in photographing from nature or from a drawing half-tones will be reproduced in lines and stipples available for any kind of printing. As these plates or sheets are waterproof they can also be used as surfaces upon which can be printed or produced all kinds of ornamental and useful work.

Having now described and particularly ascertained the nature of my said invention, and the manner in which the same is or may be used or carried into effect, I would observe, in conclusion, that what I consider to be novel and original, and therefore claim as the invention secured to me by the hereinbefore in part recited letter patent is—the manufacture of pliable plates or surfaces by treating paper or other fabric in the manner hereinbefore described.

ON BICHROMATED GELATINE FILMS AND THE STANNOTYPE PROCESS.

[A communication to the Glasgow and West of Scotland Amateur Photographic Association.]

THE action of light on the bichromates in presence of organic matter has been known for a very considerable period. Mungo Ponton, in 1839, was the first to base a process on this reaction. He applied a solution of potassium bichromate to paper, dried it in the dark, and on exposing to light he found that it darkened very considerably. The chromic acid in the salt was reduced to chromic oxide. Placing paper prepared in this manner behind a copperplate engraving, and exposing to light, a negative copy of the engraving was obtained. To fix such a picture all that was necessary was to wash in water so as to dissolve away the unaltered bichromate. Here is a print obtained in a similar manner from a copperplate engraving, and which you see is a negative reproduction that is capable of producing in its turn a picture having the lights and shades as in the original.

Becquerel (1840) demonstrated that the reduction of the bichromate was due to the presence of the size in the paper. He devised a process which consisted in mixing the bichromate with starch paste and applying it to paper. On exposing to light under a copperplate engraving, and afterwards immersing in an alcoholic solution of iodine, a blue reproduction of the engraving was obtained. The *rationale* of this change was due to the fact that in those parts where the light had not penetrated (the dark parts of the engraving) the starch remained unaltered, and was able to form blue iodide of starch. This iodide of starch is, however, a very unstable substance, and although the picture appears strong enough when wet, it loses a good deal of its character in drying, changing from blue to a pale violet. Here is one of Becquerel's pictures.

Hunt worked also with the bichromates, and to the various processes he brought forward he gave the generic name of "chromatype." They consist essentially in forming a chromate of copper in the paper, and, after exposure behind the engraving, developing the picture by means of gold, silver, or mercury salts. Some of these early light pictures I have here reproduced.

While it was sufficiently apparent that light had wrought a change in the bichromate employed in these examples, it was further discovered that the organic matter was itself altered in its physical character; in fact, Becquerel's method of producing a picture with the lights and shades the same as the original, shows clearly that the starch had been acted on where the light had access in such a way as to lose its characteristic property of forming a blue compound with iodine. Mixed with a bichromate and exposed to light, gelatine, gum, starch, albumen, &c, were all found to be rendered insoluble.

Now, what is the cause of this insolubility? Two theories have been put forward to account for it:—1st. That the organic matter is oxidised at the expense of the chromate which is reduced to chromic oxide, and the insoluble body is virtually oxidised organic matter.—2nd. That the organic matter forms a true compound with the chromic oxide reduced by light. This view was first propounded by Mr. J. W. Swan, of Newcastle, in a paper read before the Photographic Society of Great Britain on May 10th, 1870, and it is the one which has the most evidence in its favour. There is, however, much complexity involved in the chemistry of the matter.

Mr. J. Spiller has been making some experiments with the various chromates and bichromates with a view to unravel some of these reactions, and those interested will find a short article by the gentleman in question in the *Year Book* for the current year, giving some details of what he has done and intends doing.

In addition to the prints already shown, where bichromate of potash has been employed as the sensitising agent, I have one or two here prepared with ammonium bichromate and the normal chromate of ammonium. In the case of normal chromate, or yellow chromate of potash, light has no great reducing action. In the case of the normal chromate ammonium it is a very sensitive body indeed. A very curious fact in connection with these changes was demonstrated by Captain Abney. Taking a piece of paper coated with gelatine rendered insoluble by alum and duly sensitised with a bichromate, and exposing under a negative, he placed it in contact with a piece of carbon also impregnated with a bichromate, and the two surfaces were kept in the dark and under pressure for some ten to twelve hours. The paper that had received the impress of light communicated the action which the light had started to the pigmented tissue, the result being that a picture is obtainable on the film which had never been exposed to light.

The great experimenter in this field of work was undoubtedly the French chemist, Poitevin. It is by his researches more than by any other that the whole superstructure of carbon printing, autotype printing, the powder processes, the various collotype or printing with lithographic ink processes, has been raised. As far back as 1848 we find Poitevin devoting himself to the production of photographic relief pictures. He named his process "helioplastie," and his *modus operandi* was as follows:—A bichromated gelatine film was exposed to light under a positive or negative, according to the nature of the relief picture wanted. It was developed by being allowed to swell in cold water, whereby those parts acted on by light refused to swell, while those that had been protected swelled. This relief picture was hardened in a solution of sulphate of iron, and, after draining, a plaster cast was taken of it. From this again, by means of a fusible composition, another casting was taken, to utilise which he coated with copper by means of a galvanic current. Poitevin, however, does not seem to have carried his researches sufficiently far to have made his process a truly practical one. In reading the record of these early experiments Poitevin seems always to have worked with gelatine in the moist state.

It is to Woodbury that we are indebted for a rational process of relief printing, and the reaction by which he obtains his reliefs is the solubility in warm water of those parts of a bichromated film which have been protected from the light. Woodbury's patent for the production of those pictures known under the name of or "Woodburytype" was taken out in 1866. We are more or less familiar with these productions, and their beauty, apart from the fact of their absolute permanence, attests the value of this very perfect photo-mechanical process. It may be interesting to note that all those pictures of actors and actresses which appear in the magazine, *The Theatre*, are done by Woodburytype. In France the process does not bear the name of its inventor, but is known under the designation of "photoglyptie." The Woodbury process, while giving such excellent results, is by no means one which amateurs could avail themselves of, as it necessitates the employment of a hydraulic press, whereby the hard gelatine relief is pressed into a bed of lead or other soft metal, which forms the printing mould. However, Woodbury, within these last two years, has brought forward a process which meets, I think, the requirements of amateurs. To this he has given the name of "stannotype," inasmuch as the relief picture is covered with tinfoil. "Tintype" might have expressed the same idea more graphically, but I think you will admit it lacks dignity.

In Woodburytype the start is made with a negative, in stannotype with a positive or transparency; and Woodbury recommends that this be produced by the carbon process. The negative from which this is produced will require to be masked, so as to give clear glass all round the finished transparency. The reason for this will be obvious as we go on. The timing of the exposure of the tissue under the negative must be regulated by a photometer, and Woodbury's form of this instrument you have here. After the exposure has been completed development of the tissue is to be made on a collodionised glass plate well washed to free it from the ether and alcohol. The tissue having been allowed to soften in water for a short period is squeegeed on to the glass plate, and, after remaining some little time in contact, the plate with the tissue is plunged into water about 95° Fahr., when the development of the picture takes place as soon as the original paper of the tissue comes away.

You thus have a positive picture reversed as regards right and left, and outside of the picture you have clear glass. The reversal of the picture at this stage is necessary, otherwise your mould would throw off reversed prints. These carbon transparencies require, as a rule, strengthening, and for this purpose a solution of permanganate of potash is made use of—a quarter of an ounce of permanganate to one pint of water. This gives a non-actinic colour to the picture the character of which you can judge of from the example I now put forward. You will see that this picture has been masked in such a way as to leave a margin of about one-eighth of an inch clear glass all round the picture. For my own convenience I have made the transparency on a whole-plate, but of course the half-plate would have been the correct size on which to have produced the transparency.

W. Lang, Jun.

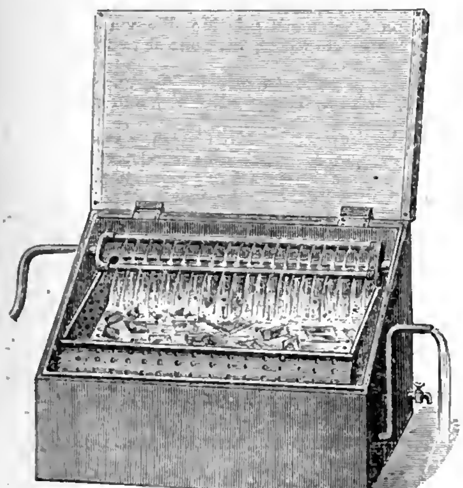
(To be concluded in our next.)

Our Editorial Table.

MARION AND CO.'S REGISTERED WASHING APPARATUS.

We have recently had the pleasure of inspecting a new apparatus for washing prints, just introduced by Messrs. Marion and Co., which possesses several novel and interesting features. The main principle of the apparatus consists in the fact that the prints are kept in constant motion during the period of washing, and this, combined with a very perfect system of in- and out-flow of the water, greatly curtails the duration of the operation, and thus contributes to the brilliancy and permanency of the prints.

The apparatus, of which we give a diagram, consists of an outer casing of wood enclosing a perforated metal vessel of peculiar form, which, in conjunction with the system of in-flow, causes the prints to partake of a constant rotary motion during the whole period of washing. As will be seen by the figure, the water is admitted by a double series of jets playing in different directions, so as to set up two separate currents. The front of the inner metallic chamber is shaped in a circular form, the result of which is that by the action of the in-flow the current takes a rotary direction, carrying the prints below the surface until they encounter the force of the second series of jets, when they are again driven into the first current. The direction of the jets may be varied to such a degree that, on the one hand, the prints may be driven into one corner of the apparatus; or, on the other, it becomes impossible for a single one to find a resting-place anywhere—in fact, so long as the water supply lasts the prints are in perpetual motion.



The out-flow is from the bottom of the outer vessel, the water entering the inner one. From this it results that a constant circulation is proceeding through the perforations of the latter, and, consequently, a most perfect and rapid diffusion of the hypo. So perfect is this diffusion that an hour's washing serves to entirely remove all traces of the obnoxious salt.

The apparatus is compact and self-contained. It can be closed and left to work by itself, requiring no attention after the in-flow and out-flow pipes have been once regulated; and, as there are no mechanical arrangements to become disarranged, there is little chance of any damage from accidental overflow. The apparatus, which is registered, is made in various sizes to suit different requirements, and we can recommend those of our readers who are in search of such a thing to pay a visit to Messrs. Marion and Co.'s establishment.

"LUTHER MILLER'S AMBITION," AND "TWO SAXON MAIDENS."

These are two volumes which have been sent to us by the Wesleyan Methodist Sunday School Union. With their literary merits we need not concern ourselves, the *raison d'être* of their being submitted to us consisting in the photographic aid that has been lent to certain illustrations with which they are embellished, the process of "ink-photo." printing having been pressed into the service.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the technical meeting of this Society, held on Tuesday last, the 25th instant, the chair was occupied by Mr. J. Spiller, F.C.S., Vice-President.

A question was read, emanating from Mr. W. M. Ashman:—"Information is desired as to the probable cause of the albumen leaving the surface of the paper in the case of prints," a number of which were shown. These prints were sent up to Mr. Ashman from a well-known large establishment, and the effect was certainly very curious. In parts the surface of the paper appeared to be gone, as though two prints had been stuck together and torn apart. The appearance came on in the washing, when the surface was so soft that it might be rubbed away.

Mr. T. Sebastian Davis inquired whether the strength of the bath upon which the paper had been floated was known.

Mr. Ashman replied that he had no information on that head.

Mr. Davis thought that the bath was probably too weak.

Mr. W. England suggested that the paper might have been doubly albumenised, and that the two coats had separated.

Mr. Ashman said that samples of the same paper had been sent to him, and he had not found the disintegration to occur. He thought that the paper had been sensitised in too cold a room, in consequence of which the bath had its tenacity or hold upon the paper. Some two years ago, when sensitising in very cold weather, the same thing had happened with him. If the drying-room had been kept at a temperature of 60° he thought that the bad result would not have occurred.

Mr. England thought hard sizing of the paper might account for the result. With Saxe paper such a thing did not happen.

Another question was read:—"In using Mr. Spiller's method of reducing the intensity of gelatine negatives by a solution of salt, alum, and sulphate of copper, may the same liquid be used a second time?"

The Chairman said that all the ingredients were so inexpensive that it was not worth while to do so; the strength would be reduced by use, and the operator would not, with a varying solution, so well know what he was about.

Mr. Ashman showed a printing-frame for holding opal plates in register-ing with the negative, so that the course of the printing might be watched. He produced a print upon opal glass which had been, in the course of of printing, lifted and replaced six times, and no indication of shift was perceptible. A description of this frame will be found in our report of the London and Provincial Photographic Association.

The Chairman considered the idea a very good one.

Mr. Best showed some cabinet portraits illustrating the difference of width and length produced by cutting the paper the length or cross way of the sheet.

Mr. W. E. Debenham observed that the immediate cause of the difference was not the cutting of the paper, but the mounting of the prints when damp. If they were dried and mounted in the manner shown some time since by Mr. A. Cowan, they would be alike, whichever way the paper had been cut. As it was, neither those which seemed the longer nor those which appeared the broader were true, but a medium between them would be.

Mr. F. W. Donkin measured the prints, and found the difference to be about seven millimetres in 150, or nearly five per cent. The actual distortion would be half that amount.

Mr. Debenham then showed a folding lantern for travelling. For a friend whose eyes had suffered from the red light given by the cherry fabric with which it had been originally fitted, he had substituted deep yellow paper and two thicknesses of the green oiled silk sold at chemists' for surgical purposes. Of the two illuminating sides one was furnished with a single thickness of the yellow paper in addition to the silk, and the other side with two thicknesses. A candle was placed inside.

The Chairman considered the light through the double paper side sufficient to read by and ample for development.

A negative was produced which had been developed with the dish about six inches distant from the light without showing any indication of light fog. The plate was a quick one of about three times the rapidity of the average rapid commercial plate.

It was inquired:—What was a proper test for judging of the visual luminosity of any particular light.

Mr. Debenham said that he had judged from the ease with which he could see the details of a negative; but a book might be used, and the distance noted at which certain type could be read. Plates exposed a given time at this reading distance could then be developed together and examined as to which gave the least image.

Mr. T. Bolas remarked that the printed matter used should be black and white, as colours would show with varying distinctness under lights of different colours.

Mr. Debenham said that a gelatine plate was yellowish, and he thought that to be more exact the paper should be as nearly as possible of the same colour.

The Chairman remarked that he had a work on photography, published in 1854, in which gelatine was mentioned as a vehicle for the photographic image. He believed that that was the first publication of the suggestion. It was mentioned as the objection to its use that, although the image came out well, the film dissolved in the developer.

Mr. Bolas observed that that was Poitevin's process.

Mr. Herbert B. Berkeley showed a spring shutter, known as Reynolds and Branson's. An adaptation had now been added which enabled the operator to give at choice, instead of the very rapid exposure, a controlled one of from one-quarter of a second to three seconds.

On the subject of measuring the speed of shutters being discussed,

Mr. Debenham said that Mr. A. Haddon had measured one which he had in use, and found that from the commencement of the opening of the lens until it was quite closed occupied $\frac{1}{35}$ of a second. As the lens was only entirely open a very small portion of this time, it was about equal to an exposure of $\frac{1}{70}$ of a second if the lens had been entirely open all the time. The means employed by Mr. Haddon was a vibrating spring furnished with a bristle, which registered its motion upon a smoked glass.

Mr. C. Ray Woods said that Captain Abney had described this method before the Society of Arts about three years ago, but with the difference that he used a tuning-fork, which was superior to a spring, as the rate of its vibrations was known.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 20th instant, the chair was occupied by Mr. J. Traill Taylor.

Mr. W. M. Ashman showed a frame for use when printing upon gelatino-chloride plates, made by himself from the construction of Mr. Offord. An ordinary half-plate printing-frame of the kind in general use is taken, and a plate is put in as a bed for any smaller-sized negative: close to the ends of the plate, and as near to the corners as the frame will permit, four pins are inserted vertically into the wooden frame. The back consists of a sheet of metal, such as ferrotype plate, pierced with holes to fit on the pins and ensure registration. On the middle of this back is a broad ring of india-rubber, which, being firmly riveted to the metal back with a metal ring or washer between it and the sheet metal, is depressed in the centre and forms a sucker or pneumatic holder for lifting the opal for examination, and replacing it in the same position upon the negative. The ordinary back is then put in place and fastened down by springs as usual.

Mr. A. L. Henderson said he thought the old plan of working against fixed stops was better, as there was then no play and the registration was consequently truer.

Mr. A. Cowan considered that there was an advantage in some such arrangement as the one exhibited, as it prevented any sliding motion of the two surfaces of the negative and transparency. This sliding movement with both surfaces was very liable to produce scratches. He (Mr. Cowan) then handed round a portrait negative taken on a plate given him for trial by Mr. Henderson. The exposure had been one second and a-half, with diaphragm $\frac{f}{8}$ or No. 4 on the universal system. An ordinary rapid commercial plate under the same conditions required three times the exposure which had been sufficient for this one.

Mr. Henderson said that the plate was prepared by a method of which he would give details at a future meeting. For the present, however, he would state that there was a new departure, in that the silver bromide had been formed by double decomposition, in the absence of all colloid bodies, the gelatine being subsequently added.

Mr. J. B. B. Wellington inquired whether there was much silver in the emulsion.

Mr. Henderson replied that there was 240 grains of nitrate to fifteen ounces; and, in answer to another querist, said that it had been added to the gelatine at a temperature of 120°.

Mr. A. Haddon remarked that some years back it had been suggested to form the bromide from chromate of silver.

Mr. Henderson said that an easy method of making a pellicle negative was to stretch fine paper—such as that known as *papier mineral* —over a glass plate and paste the edges over the back. When dry, the plate was coated with emulsion in the usual way, and could at any time be separated from the glass by cutting round the edge.

The Chairman said that the objection to paper for negatives on account of its grain was not so real as was supposed. He had seen Talbotype negatives where the paper grain did not prevent the titles of books, which were in a picture of a library, from being legibly depicted. With the gelatino-bromide process, as the image was upon, and not in, the paper, the grain should be even less objectionable. *Papier mineral* was, he believed, made translucent with paraffine; but he would be glad if any gentleman gave details of its preparation.

Mr. W. Coles said that a firm who prepared gelatino-bromide paper for negatives had two negatives on views—one on glass and one on paper. Prints from these were shown to those likely to be interested, and in most cases they selected the print from the paper negative as that which they would consider to have been produced from the glass one.

Mr. Mous thought that if the paper were made transparent with castor oil in ether the grain would not show. Some time since he had exhibited prints at this Association which had been made from negatives thus prepared.

Mr. J. J. Briginshaw showed a lantern transparency of French manufacture, the two glasses of which were only as thick as one ordinary glass. This made such slides very portable.

Mr. Cowan said that there was great difficulty in obtaining such thin glass, and the price was about four times that of glass of ordinary thickness.

Mr. W. E. Debenham observed that, while both glasses were thin, one was much thinner than the other. A question being asked as to ready-sensitised paper,

Mr. W. M. Ayres said he considered it inferior to that which could be sensitised in the ordinary way, and as it contained less silver the prints upon it were not so likely to be permanent. In his own practice he used a sixty-grain bath, floated for three minutes, and added one ounce of silver for every ten sheets sensitised.

Mr. Debenham formerly used a sixty-grain bath, and floated for three minutes, but, with paper now sold, he found a forty-grain solution bath and floating one or two minutes to answer better. After each six sheets had been floated, two ounces of a ninety-grain solution of silver were added, which kept up the strength and quantity.

Mr. R. Chipperfield and Mr. F. G. Nichols were elected members of the Association.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

This Society had a special lantern evening on Thursday, the 20th instant, at which there was a very large attendance of members and their friends. Mr. J. C. Cox presided.

The principal feature of the exhibition was a lantern slide competition open to members, the number of slides being limited to three each. Voting papers were distributed amongst the members present, and 300 marks were allowed to each voter for each set of three slides. The following were the results of the voting:—Jno. Mathewson, 4,111 marks; D. Ireland, 3,980; D. Ireland, Jun., 3,961; J. Y. Rogers, 2,595; A. Simpson, 2,532; J. R. Wilson, 2,355; W. M. Martin, 2,002.

Many of the slides were on Chapman's gelatino-albumen plates and several on Cowan's chloride plates—the whole, with one or two exceptions, reflecting great credit on the exhibitors.

A lantern exhibition then followed, to which Messrs. Valentine, Mathewson, Ireland, Wilson, Martin, Rogers, Ritchie, and others contributed.

A frame of transparencies, kindly sent by Mr. Cowan, was shown and very much admired, and several members expressed their determination to make a trial of these plates, which as yet are not in general use here.

Mr. Jno. W. Lawdon exhibited and explained a new American camera, embodying a number of ingenious movements.

The usual votes of thanks brought an exceedingly enjoyable evening to a close.

BERLIN ASSOCIATION FOR THE CULTIVATION OF PHOTOGRAPHY.

This Association met on the 15th ultimo,—Professor H. W. Vogel, President, in the chair.

The Chairman read the programme of an industrial and electrical exhibition which is to take place in August, at Teplitz. He then showed a number of photographic views of Colorado, by Mr. Jackson, of Denver, and afterwards reported concerning his experiments with two of Dallmeyer's wide-angle lenses.

Herr Geheimrath Busse, director of the State printing establishment, showed a number of excellent *photogravures* printed in that establishment, representing statuary and other objects, principally antiquities belonging to the royal museum.

The Chairman exhibited a couple of photographs of coloured pictures—one an old Italian fresco, and the other a fresco by Cornelius. These pictures were photographed in the one case by a Berlin firm with ordinary collodion, and in the other by M. Braun, of Dornach, with collodion especially intended for photographing coloured objects by staining the collodion film. The result obtained in the last case was pronounced quite a photographic triumph, the subject appearing with great fidelity.

Some annoyance the Chairman had experienced in connection with a recent case in which he was referee brought up the subject of the payment or non-payment by the customer for a sitting when the proofs resulting did not give satisfaction.

The subject was discussed at some length, the general feeling seeming to be that in the long run it would do the photographer more harm to exact payment in such cases than he should gain by the small sum he would obtain.

A variety of subjects of no general interest were then discussed.

Herr Joop recommended a reducer of the following proportions:—Ferrous oxalate developer, two parts; concentrated solution of cyanide of potassium, one part. The latter must be filtered, otherwise a grey precipitate will form upon the film.

The Chairman remarked that he preferred to use iodine water for reducing plates.

Shortly afterwards the meeting was adjourned.

Notes and Queries.

Suttonian is a beginner, and finds that his fingers become stained by the developer to a greater extent than he likes.——He should obtain rubber finger-stalls, which are sold for photographers' use by most dealers.

"Southend" encloses two ferrotypes, both badly fogged. It is evident that his silver bath is quite out of order. Let him neutralise it with bicarbonate of soda, expose to sunlight for a few hours, then filter and acidulate. During the time it is being subjected to this treatment he ought to make use of a new bath. In reply to another query: there are no plates sold ready sensitised on which to obtain collodion positives.

THE REV. B. P. is desirous of ascertaining a reliable process for silvering a glass concave mirror which he has had ground for photo-astronomical purposes, and wishes to be referred to any good formula for this purpose. We advise him to procure copies of our ALMANACS for the years 1873 and 1879 respectively, and in these he will find two processes nearly allied to each other, both of which are equally good.

"Is there a reasonable chance of a collodion transfer remaining unchanged for a few years? Or do you consider an enlargement upon gelatino-chloride (or bromide) paper likely to be more durable?—FRED. B. RUSHTON."——There is no reason why an enlargement made according to either of these systems will not last several years, provided care be taken in the manipulations. It has been stated that collodion transfers fade; but, in most cases, these have been specimens finished in transparent oil colours, many of which colours, as known to artists, will bleach on exposure to strong light. But this does not prove that the photographs in themselves fade. What we have said applies to gelatine as well as to collodion pictures.

S. S. K. inquires:—"What advantage is claimed on behalf of carbonate of soda over ammonia in alkaline development? I have tried both methods most carefully, and find that the soda developer necessitates a lenger exposure being given to the negative than when ammonia is employed. What, then, constitutes its advantages, and have others found the same thing to result from its use?"——In reply: Mr. H. J. Newton, who is one of the most strenuous advocates of soda, claims that it is more stable in its action, and that the developing power is more continuous, if rather slow. We do not think that many photographers have recognised in it the possession of any virtue over ammonia, which, from its greater energy, occupies the position of prime favourite. The yellow stain imparted to the gelatine film by soda development is also by many held to be objectionable, although it can doubtless be removed by treatment with hydrochloric or oxalic acid and alum.

PYRO. asks:—"Are there any means by which I can effectively mask or otherwise alter a negative so as to cause it to print less harshly than it does at present? It was made by the collodion process, and is varnished."——We advise that the intensity of the negative be equalised in the following manner:—Make the back quite clean, and give it a coating of greatly-diluted albumen, following with an application of collodio-chloride. When dry, expose to a diffused light through the negative film. It is obvious that the shadows or transparent portions of the negative only will be acted on in the greatest degree by the light, the strong lights undergoing no alteration. When this process of equalising has been seen to have proceeded far enough, apply a weak solution of cyanide of potassium to the collodio-chloride to fix the image thus produced on the back of the glass, and which will serve as a mask for effecting the subduing of the harshness or intensity complained of by our correspondent.

"I HAVE been trying a dusting-on process for producing portraits on opal glass plates and have not been successful. I may, in fact, say that I have been unsuccessful in a singular degree. The formula I adopted was—

Saturated solution of potassium bichromate	4 drachms.
Albumen	4 ,,
Water	1 pint.

I exposed under a negative and obtained a visible image. I then took the print into a damp room and applied a fine powder by means of a soft brush, but none would adhere. Where am I wrong?—J. F. D."——In reply: Our correspondent has omitted an important ingredient in his sensitive mixture, viz., honey, or grape sugar. Let him add three or four drachms of honey to the above, and he will succeed in forming a surface to which powder will adhere when applied in the manner described. But by this process he will, from a *negative*, obtain only another negative. For opal glass portraiture he must employ a transparency, not a negative.

W. B., writing for information concerning the relative covering powers of the triple achromatic and the single landscape objective, says:—"I have not proper appliances for ascertaining the difference between them; but in looking over some literature of a former period in my possession I find that opinions appear to have been then divided as to their relative merits in this respect. May I trouble you for information as to how the question stands at present? I have been out of photographic practice for several years, which may account for ignorance on a subject that I presume is now well known."——In reply: Since our correspondent retired from the active pursuit of the art many changes and improvements have been made in the optical branch of photography, including the discontinuance of the manufacture of the "triple" lens mentioned. But, as between it and the single achromatic landscape lens, there is not a shadow of doubt that the latter will embrace a much wider angle of view; and the deeper the meniscus form of the lens the greater will be the included angle, because the diaphragm may then be brought closer to the anterior surface of the lens.

THE REV. DR. BROWNE writes:—"I have been in the same trouble with regard to blackening brass that your correspondent Mr. Conway has sought advice upon. Many months ago a method appeared in the Journal, which, unfortunately, I have lost. My method of working was to dissolve copper wire in nitric acid [N.B.: do not perform this operation indoors] until it would take no more. I then carefully cleaned the brass, heated it over a Fletcher's gas burner, dipped it in the strong nitrate of copper, when a considerable efflorescence went on for five minutes or so, removed it to the gas burner, and heated. The result was that where there was an amount of nitric acid left on the brass the heat converted it into green crystals easily rubbed off, and the whole operation was a failure. Where was I wrong? I have just made a new set of diaphragms for one of my lenses, and it is very discouraging, after cutting the openings to almost perfect exactness—thanks to the slide-rest in my lathe—not to be able to finish them with the same black stain that our opticians are such adepts in."——We shall endeavour to have some practical remarks on the subject of staining brass in an early number.

G. F. V.—Our correspondent desires to photograph gold and silver brooches the same size as the original, and is at a loss how to effect this end.——He should ascertain the focus of the lens he employs, and extend the camera so that the ground glass be twice that distance from the lens, the brooch being an equal distance in front. The photograph will then be the same size as the original.

A BOTHERED PHOTOGRAPHER writes:—"Upon looking over a number of negatives I took when in Portugal seven years ago, I am greatly annoyed to find several of them covered all over with a perfect network of cracks, as if the film had shrunk and cracked. Is there any remedy, such as causing the film to expand, and thus have its parts joined together once more? The cracks are exceedingly fine, but for all that they show very badly. Would immersion in alcohol or ether be of any use?"——In reply: By treating the film with alcohol and ether it would all dissolve away. The proper treatment consists in charging a pledget of cotton wool with lampblack and rubbing with a circular motion all over the surface. By doing so every crack will immediately disappear. Then pack the negatives with a sheet of blotting-paper between each, and no further cracking will occur.

Exchange Column.

Wanted, a binocular microscope in exchange for slides, cells, troughs, &c —Address, W. H., 2, York-street, Covent-garden, London.

Wanted to exchange, interior cabinet background, by Marion, for seascape same size.—Address, F. JACKSON, 16, St. Alban's-terrace, Sherwood-street, Nottingham.

Wanted, a complete tourist's set of photographic apparatus in exchange for opals, vignettes, cutting-shapes, &c. — Address, W., 2, York-street, Covent-garden, London.

Wanted, a *Le Merctoire* camera, in exchange for a strong home-made camera, half-plate, and part cash.—Address, A. CHAMBERS, 8, Gordon-road, West-hill, Hastings.

I will exchange a gentleman's gold hunting-watch and gold Albert chain for a cabinet or whole-plate lens by a good maker.—Address, C. T., 36, Orbel-street, Battersea Park.

I will exchange a cabinet burnisher and cabinet rolling-press, equal to new also cabinet lens. What offers in accessories?—Address, G. A. ROBINSON, 1, St. Mary's-place, Castlegate, Berwick-on-Tweed.

I will exchange some modern oil and water-colour drawings, framed, and cash, for an $8\frac{1}{2} \times 6\frac{1}{2}$ tourist camera and Ross's rapid rectilinear lens for same.—Address, JAMES MALINS, Crosswood, Aberystwyth, S. Wales.

I will exchange a sliding-body, half-plate camera, a 5×4 porcelain water-tight bath, and a repeating-back for a quarter-plate camera. Wanted, a half-plate landscape set.—Address, KENYON, Church-street, Blackburn.

I will exchange a whole-plate portrait lens, two quarter-plate ditto, all fitted with Waterhouse diaphragms, and in condition equal to new, for a quarter-plate portrait lens by a good maker.—Address, C. VERNON, Tonbridge-road, Maidstone, Kent.

Wanted to exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, from January, 1882, to October, 1883, for rack and pinion or winch screw suitable for quarter-plate camera. — Address, G. LYONS, 12, Little George-street, Portman-square, W.

I will exchange a 15×13 photographic rolling-press, by Knox, of Glasgow, new last season, good condition, guaranteed, cost £7 10s., for a 12×10 Rouch's bellows-body camera, which must be in good condition.—Address, W. WESTOBY, St. John-street, Goole.

I will exchange a splendid new interior Seavey's background for any good studio accessories or a Dallmeyer's $8\frac{1}{2} \times 6\frac{1}{2}$ rapid rectilinear or Ross's rapid symmetrical lens, same size; difference in price adjusted.—Address, W. M. HARRISON, Falmouth, Cornwall.

Wanted, offers of accessories in exchange for the following:—Wall background, by Marion, interior and seascape, by Seavey, also whole-plate lens, by Slater, good for cabinets, and splendid half-plate view lens.—Address, J. WHITE, 32, High-street, Littlehampton.

I will exchange a whole-plate short-focus "J. S." portrait lens, perfect condition, cost £5 last summer second-hand, with rack focus, for Lancaster's or other half-plate set and small rectilinear or symmetrical, or offers.—Address, E. BASIBE, 10, Wellington-street, Gloucester.

What offers for 126 numbers of THE BRITISH JOURNAL OF PHOTOGRAPHY, from 1881 to 1883? I will exchange a good, old violin and bow, grand tone, fit for a soloist, worth three guineas, for accessories, also a good guitar, patent head.—Address, D. BLAGROVE, 73, High-street, Lewes.

Wanted, a small gem camera and lenses, also a large camera not less than 18×16 (if the dark slide is in good condition other part not of so much consequence) in exchange for first-class printing-frames and accessories; or what offers for same?—Address, C. R. TRUEMAN, Southwold, Suffolk.

I will exchange a Ross's No. 2 *carte* lens and a quarter-plate mahogany camera, good as new, cost £7 15s., also a portable dark box to carry same and develope in. What offers together or separate? A half-plate bellows-body camera, with two backs, preferred.—Address, SULPHITE, 52, Goldsmith-road, Peckham, London.

I will exchange Jones's £9 sewing-machine, also a balcony, five pieces, and a good photographic desk (photograph sent), for interior and exterior backgrounds, posing-chair, No. 3 or 4 rapid rectilinear lens, 15×12 bellows-body camera, or anything useful in photography; offers requested.—Address, W., photographer, Ropergate, Pontefract.

I will exchange a mahogany sliding-body camera, for plates $6\frac{1}{2} \times 4\frac{1}{4}$, with three dark slides, and a quarter-plate portrait lens, all by Hocking and Co., also a portable tripod, with sliding legs, and an air-tight glass bath, with dipper, for plates 10×8, with a quantity of silver solution, for a good 10×8 or larger size bellows-body camera.—Address, THOS. HIRST, Main-street, Ledbergh, Yorkshire.

I will exchange a gem camera, with twelve lenses, to take twelve, twenty-four, or thirty-six on a plate, in good order, also a Ross's compound portrait lens for *cartes*, very rapid, very good for taking babies or ordinary photographs in a short studio, and for copying, equal to new, for an $8\frac{1}{2} \times 6\frac{1}{2}$ bellows-body camera, with three double backs, must be very light and modern, or a good landscape lens, or two, either single or double, by a good maker, 10×8; will either give or take cash.—Address, W. Ferguson, photographer, Keswick.

Wanted, a half-plate and a whole-plate camera (or larger), with bellows-bodies, swing-backs, rising-fronts, and three or more double backs to each camera, also tripods for same, Dallmeyer's rapid rectilinear, Ross's rapid symmetrical, or other good lenses by same makers, suitable for the cameras mentioned, also hot rolling-press by a good maker, in exchange for Wheeler and Wilson's No. 6 sewing-machine, equal to new, having only been used a few times, a number of Bewick's prints, first-class mahogany supper tray and stand, bronze tea urn, gasogene, also the following books:—*Circle of the Sciences*, two vols., *Art Journal*, two vols., *History of Protestantism*, three vols., *Shakespeare's Works*, eight divisions, published by Mackenzie, or other valuable exchange.—Address, William L. Knott, 68, King-street, North Shields.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

*** Several articles in type are left over this week, and we ask the forbearance of contributors during the present pressure on our space.

E. E. Hibling.—We regret our inability to render you effective aid.

T. G. S.—The address is "Optician, Lord-street, Liverpool." Thanks for enclosure.

W. G. (San Remo).—The gentleman named is at present in America. The address, "Florence, Italy," is sufficient.

London.—The affair appears to be a hoax. Have nothing to do with it, or you may find yourself become the laughing-stock of your neighbours.

R. Sedgfield.—Thymol, or thymic acid, is derived from thyme. It may safely be employed for the purpose you suggest. It will be quite inert on the photographs.

G. J. Hill.—You are not the only one who has experienced a difficulty in electrotyping on a gelatine film. More perfect blackleading is the best suggestion we can make.

A. G. B.—We know nothing more than is stated in the communication referred to. That form of shutter, we fear, cannot be made to work in so short a time as you require.

B. Bennett (Galway).—Messrs. Stanton Brothers, Shoe-lane, E.C., will probably supply tinfoil the size you require. If they cannot, we know not where you will be able to procure it.

Stephen.—If the wooden vessels are not to contain hot solutions there is nothing better than paraffine wax for coating them with. If you require them for hot solutions your best plan will be to line them with thin sheet lead.

Tyro.—1 and 2. Neither of the lenses are suitable for drop-shutter work. It is better to procure one of the "rapid" type, which will enable you to work with a larger aperture.—3. There is no method by which the stains can be removed.

S. Rhodes.—The process looks very well on paper, and many have tried to put it in practice: but, so far as we are aware, no one has yet succeeded. However, the theory is correct, and you may possibly succeed with more extended practice.

A. J. Worsley.—The metallic spots on the drawing-paper, after it is sensitised, is caused by small particles of metal in the paper itself. There is no remedy but to discard the paper and procure a fresh sample from another source.

A. S. B. (York).—If the collodion become red immediately the iodiser is added it shows that free acid is present. In all probability you have not washed the pyroxyline sufficiently. Test it with litmus paper, and if our surmise prove correct the remedy is obvious.

T. P. B.—If you are successful in coating small sizes of glass we do not see why you should meet with a difficulty in sizes of such moderate dimensions as those to which you refer. Probably a larger coating vessel is all that is required, together with a little more practice.

Mungo.—There is no practical method, that we are aware of, by which you can print in silver on real ivory. You might possibly succeed by transferring a collodion picture picture on to it—*à la* collodion transfer; but this, we surmise, will scarcely answer your requirements.

Ixion.—From your description we imagine that, at some stage of the development, light has been allowed to act upon the plates. If not, we cannot suggest the cause of the tinting. The opaque deposit is doubtless due to oxalate of lime. A little dilute hydrochloric acid will remove that.

G. H. Weatherly.—India-rubber solution is a very good mountant for photographs, except that, after they have been mounted for a time, the rubber is liable to "perish," and then the prints leave the mounts. Were it not for this, india-rubber would be largely employed for mounting purposes, as it does not cause expansion of the paper like aqueous mountants.

G. Weller.—If the gas-bag has perished to the extent described there is no means of repairing it so as to render it again serviceable. If you attempt to patch it up you will find it will always be leaking in fresh places, entailing, consequently, a great waste of gas, and possibly causing you to break down in the midst of an entertainment. Our advice is—Do not purchase second-hand bags in future without a thorough examination.

S. Sidey.—The address is "G. M. Kenyon, Esq., M.D., The Poplars, Fluker's Brook, Chester."

B. J. T.—The spots on the collodion transfers are clearly due to specks of coarse particles in the paper to which you have transferred the picture. Of this you may satisfy yourself by examining the back of the paper, and you will see that they go quite through. To avoid such defects in future you will have to employ a better quality of paper. Saxe or Rives paper—or, indeed, any paper of good quality—is free from these imperfections.

Received.—*Universal Attraction: its Relation to the Chemical Elements.* In our next.

Photographic Club.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, April 2nd, the subject for discussion will be—*On the Best Lenses for Large Portraits on Gelatine Plates.*

South London Photographic Society.—At the next meeting of this Society, to be held at the Rooms of the Society of Arts, John-street, Adelphi, on Thursday next, April 3rd, at eight o'clock, Messrs. C. and F. Darker will exhibit some objects in the lantern polariscope; and the following (from the question-box) will be discussed:—*Does the Burnishing of Prints Produce any Chemical Change in them?*

A Difficulty Overcome.—M. D——, a photographer at Eidhoven, had made a dozen *cartes* for a gentleman living at Walkenswaard. When about to send them off he discovered that he had forgotten the name of his client. What was he to do? After he had long but uselessly racked his brain he at length uttered a sigh of relief. He gummed one of the likenesses on the envelope and wrote underneath:—"To the above gentleman in Walkenswaard." The *cartes* were duly delivered.

Opening of Studio for Lochee Amateur Photographic Club.—There has just been erected in Marshall-street a new studio for the Lochee Photographic Club. The studio is an exceedingly neat and commodious structure, and is fitted with all the most recent appliances for the efficient prosecution of the art. On Tuesday evening, the 17th inst., the formal opening took place, when there was a large attendance of members. Bailie Ogilvie, the President of the Club, occupied the chair, and, in the course of a brief opening address, congratulated the members upon the realisation of their great desideratum—a studio. He referred to the success which had attended the club since its commencement in April last, the membership at present being thirty. The ample facilities they now possessed for carrying on their photographic studies and experiments would, he had no doubt, be taken advantage of, and the club in this way would have its efficiency and influence largely extended. They would be all most willing to afford every information and help in their power to beginners who might connect themselves with the Club. After consideration, certain rules for the guidance of members in using the studio were agreed to by the meeting. Seven gentlemen were also proposed for membership. Mr. Robert Keir, in proposing a vote of thanks to the Chairman, referred to the great interest he had taken in the development of the Club and in the erection of the studio. But for the Bailie's enthusiastic encouragement of the venture the Club would not have prospered so remarkably. This Club has our best wishes for its continued prosperity.

METEOROLOGICAL REPORT.

Observations taken at 406, Strand, by J. H. Steward, Optician,
For two Weeks ending March 26, 1884.
These Observations are Taken at 8.30 a.m.

March	Barometer.	Wind.	Dry Bulb.	Wet Bulb.	Max. Solar Rad.	Max Shade Temp.	Min. Tem.	Remarks.
13	30·08	SW	49	47	—	57	43	Cloudy.
14	30·17	S	50	47	—	61	47	Cloudy.
15	30·12	SW	53	50	—	68	49	Foggy.

CONTENTS.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1248. Vol. XXXI.—APRIL 4, 1884.

IMITATION OPALS.

The recent advances in popularity of both bromide and chloride gelatine dry plates for positive work, either in the form of transparencies or opals, marks a new era in the practice of many professional photographers, and has caused an increased demand on the part of the public for a class of picture that has not hitherto been greatly patronised except by a select few. In fact the opal picture has until quite recently been almost the speciality of the more aristocratic amongst our professionals, whose *clientèle* comprises those classes whose pockets enable them to pay high prices.

The introduction of gelatino-bromide and gelatino-chloride opal plates has caused a change. Not only is the price so moderate, and the consumer saved so great a proportion of the trouble involved in the production of the pictures, but the results are rendered far more certain than was formerly the case when wet collodion and pyro. development was almost universally adopted. Then it was almost a necessity to retain a special operator, whose sole duty consisted in making opal enlargements, and competent artists of that class were always able to command large salaries; consequently, it was, with rare exceptions, that the production of opal pictures was confined to photographers of the first class.

With the modern dry plates as supplied commercially the greatest difficulties in manipulation are entirely removed, and the production of a positive image suitable for opal—that is to say, an image of suitable tone—is as easy as the development of a negative. The operator who can perform one duty is equally competent to undertake the other. But still many professionals are deterred from embarking extensively in the opal business, because their clients can not or will not pay a price which will reimburse them for the extra cost of opal glass.

Many attempts have been made in previous years to introduce substitutes for opal glass, with more or less success; and there seems to be now a renewed demand for some method by which results at least approaching those on opal glass can be obtained. Probably none of the methods yet introduced can be said to equal the real article, owing to some peculiarity of the tint of the opal, which is never quite matched; but we shall mention one or two simple methods by which a very close approximation to opal pictures can be effected. These are based upon the employment of an emulsion containing a white pigment, which renders it opaque, and which may be applied to the glass either before or after the picture is produced. Its tint may be varied at will, as will be shown, and in all cases it will be in optical contact with the picture.

Some few years ago a number of so-called "imitation opals" were exhibited at a meeting of one of the metropolitan societies, the basis of their production being a collodion transparency backed with paper; but the results were so wretchedly poor that few cared to examine them twice. The fault lay in the paper backing and the method of cementation to the glass—the mountant having partially sunk into the paper, destroying the purity of its colour and bringing out painfully the irregularities of its texture. With an emulsion there is, if properly managed, no chance of this taking place.

The oldest plan of procedure is to form an emulsion by incorporating finely-ground sulphate of barium with gelatine. In order to secure the best results it is, of course, necessary to reduce the pigment to a state of the utmost possible fineness—an operation which requires both time and care. Those who are not afraid of the trouble may proceed as follows:—Dissolve separately in hot water one ounce of sulphate of zinc and one ounce and a-half of nitrate of barium. Mix the two solutions and allow the precipitate to settle; decant the supernatant liquid, wash the sulphate of barium in two or three changes of hot water, and then transfer to a piece of fine calico placed in a funnel to drain. Now take a sheet of ground glass and place a teaspoonful of the pasty mass on its centre and proceed to grind it, using as a muller a smaller piece of glass cemented to a wooden handle. When this is found to be fine enough it is incorporated with a warm twenty-grain solution of gelatine, and the mixture is then passed through several thicknesses of cambric to remove the coarser particles.

This method is, as we have said, a troublesome one, if an extremely fine result be required, for which reason we prefer to proceed by double decomposition. Take one ounce of gelatine, one ounce of barium nitrate, and ten ounces of water; dissolve the barium salt in the water by heat and then add the gelatine, previously swelled, and dissolve. In another vessel dissolve 300 grains of zinc sulphate in five ounces of water, and pour, with constant stirring, into the gelatine solution, just as in making a gelatino-bromide emulsion. After keeping the resulting emulsion liquid for four or five hours it is poured into a dish to set, and is then washed free of the zinc nitrate in the ordinary manner, after which it is ready for application to the glass.

Either of these emulsions may be slightly tinted to obtain a closer imitation of opal glass, different samples of which vary from bluish to pink and cream colour; but great care must be taken not to overdo this. An alternative method of tinting will be referred to further on.

A third method which, in some respects, we prefer, differs materially in the details of its manipulation, though the resulting film is identical with those produced by the plans already described. The main difference consists in the formation of the barium sulphate by a process analogous to the sensitising of a wet plate instead of by double decomposition in the vehicle itself. For this purpose take one ounce of gelatine, one ounce of barium nitrate, four ounces of glycerine, and ten ounces of water. Dissolve the barium salt in the mixed glycerine and water with heat, and then add the gelatine previously swelled. Dissolve and filter carefully.

This solution is applied in the same manner as the emulsions previously described, and allowed to set thoroughly. The purpose of the glycerine is to permit the film to set hard—that is, for some time—without the barium nitrate crystallising at the edges and elsewhere, and thus causing irregularity. When used in the proportions given it enables the film to be kept for some hours, if necessary, in a warm, dry place without crystallisation, during which time a great portion of the original water will have evaporated.

The next operation is to immerse the plate in a saturated solution of alum for from five minutes to half-an-hour, according to the thickness of the gelatine. This serves the double purpose of forming the barium sulphate by double decomposition, and of hardening or rendering insoluble the gelatine. The plate must be immersed in the solution in such a manner that the latter flows over its surface in an even wave, a flat brush or a tuft of wet cotton-wool being passed gently over the surface to remove air-bubbles. After a sufficient immersion in the alum bath the plate is again washed and left to soak for half-an-hour, when it is ready for drying.

The emulsions made in this manner may be applied to the glass as a substratum before coating with gelatino-bromide or chloride, which, of course, necessitates the preparation of the plates by the operator himself; or they may be applied after the development of the image, in which case commercial plates are available. In the one instance an unreversed image will be obtained by contact printing, in the other a reversed; this latter is of no consequence in enlarging, as the negative may be reversed, but the fact should be borne in mind.

If the barium emulsion be applied to the glass first, the result will more nearly approach that of real opal; but it will have to be observed that the utmost perfection in the gelatine surface is necessary. Dust, "pits," or other inequalities will, of course, produce their corresponding effect on the overlying emulsion film, and thus detract from the good effect. On the other hand, when applied *over* the picture, the latter must be viewed through the glass, and the charming matt effect of opals is impossible. The slight colour, moreover, of the glass is sufficient to give an unpleasant tone to the lights, which, however, may be overcome by suitably tinting the film.

Next week we shall say a few words on the mechanical portion of the manipulations.

SUBSTITUTES FOR THE LIME LIGHT.

Notwithstanding the lime light is one of the safest systems of illumination conceivable when its management is under the control of a competent person, certain accidents which have recently happened in connection with its employment appear, unfortunately, to have engendered a feeling of dislike to its use, more especially in the case of school entertainments; and this antagonistic feeling seems to be increasing rather than diminishing.

We have already heard of two cases in which applications for the use of rooms of a semi-public character for lantern entertainments have met with a negative response, this refusal being, however, subject to withdrawal if the intending exhibitors will stipulate that the lime light shall not be used in connection with the entertainment. This, as we all well know, is very arbitrary and hard, as well as unwise; still, we must accept the facts as we find them, and wait till a more intelligent wave of enlightenment sets in and drowns existing prejudices. But this leads to the contemplation of methods of illumination other than that in which oxygen directly takes part.

Marvels have already been effected during the past ten years as regards improving the intensity of illumination of lamps burning petroleum, until, at the present time, this source of illumination is sufficiently good for every purpose except that of displaying pictures on the scale of magnitude necessary for a large hall and a considerable number of spectators. For such a purpose the lime light has hitherto remained without a rival. There is no finality, however, to improvement; and, seeing that our lamp manufacturers have already effected so much, can they not do still more? Quadruple and quintuple wicks represent a very high degree of flame power, and we suppose that no gain of any appreciable value will result from a further numerical increase. The perfection of the burners in themselves being assumed, there are two directions in which we may look for further improvement. The first of these is the oil, and the second the condition of the air by which combustion is supported.

In the former times of solar and argand lamps, when fixed oils of strong body were employed, we all know how greatly the illuminating power, or at all events the purity, of their light was increased by oil having been previously saturated with camphor. Now, if sperm and colza oils of even the very finest quality be thus amenable to improvement of a marked character, it is not too much to hope that our best paraffine oils may also yet be found equally amenable to the enriching influences of either the same or other hydro carbon. This is one direction in which we may not unreasonably cherish the hope of an improvement being effected in lantern illumination.

Again: ever since the invention of the hot blast furnace the effects of heated air as a supporter of combustion in other directions than that of the furnace mentioned have been recognised, and gas-light engineers of the greatest eminence have taken, and in quite recent inventions are still taking, advantage of heated air to increase the illuminating power and purity of the flame of gas through the instrumentality of burners, which ever and anon are being brought forward and placed under the protective ægis of our patent laws.

Now, among the various lantern lamps we have examined we have not seen any application of this recognised power in the improvement of illumination, nor have we heard of any such application. This, therefore, forms a direction in which we may look for securing some increase in the illumination of oil lanterns. We throw out the idea for the consideration of lantern engineers.

An electric light having an illuminating power equal, or nearly equal, to the lime light would prove an inestimable boon to the lanternist, provided its first cost was not very considerable, and its bulk not so great as to prove an incumbrance when required to be moved from place to place. Whether the electric generator were a battery or a dynamic machine would be a matter of secondary importance, provided one could, under the conditions above-mentioned, obtain a reasonably-good light for two hours at a time. Doubtless, the most perfect system of all would be a storeage battery capable of being charged by manumotive power applied to a small magneto machine. Dynamic electricity may yet prove a friend to those who, from what motive soever, have to discontinue the employment of the lime light.

To those whose avocations and abilities lie in either of the directions indicated in the foregoing we cheerfully dedicate this article.

THE OWNERSHIP OF NEGATIVES.

In last week's issue will be found a report of an action recently tried in a court of law to decide in whom is vested the right to a photographic negative taken in the ordinary course of business. The result of this case will certainly be considered very satisfactory to most of our readers, and particularly to those correspondents who have, during the past few weeks, solicited our opinion and advice in cases where their *clientèle* have positively refused payment for their pictures unless the negatives themselves were delivered up to them. Now, several of our correspondents' cases are precisely on all fours with that which has just been tried in the Swansea County Court, except that in most of them portrait negatives are in question.

Briefly stated, the case stands thus:—Mr. Andrews, the plaintiff, a photographer of Swansea, was commissioned to take certain photographs of a vessel and of groups of her officers on board. It appears the charges amounted to a little over ten pounds, about half of which sum was for "photographing" the vessel and groups, and the remainder for duplicates supplied. The charges for the duplicates were not disputed, but payment for taking the photographs was resisted on the ground that the negatives were not delivered up to the defendant. The point, therefore, for the judge to decide was simply in whom the ownership of the negatives was vested, and this he did in favour of the photographer. The judge remarked to the defendant's advocate that when ordering a photograph, unless a special stipulation be made for the purchase of the negative, the photographer is not entitled to give it up. It was argued for the defendant that, as a special charge was made for photographing, the negative should belong to him; but the judge ruled otherwise, saying that the negative was only part of the instruments used in the production of the photographs.

The point cannot yet be considered as finally decided, inasmuch as notice of appeal against this decision was given and permission granted. Until the appeal has been heard in one of the superior courts the matter must not be considered as definitely settled. If the appeal be prosecuted (which, after the remarks of the judge, is somewhat doubtful) the point of contention will probably be that when a definite charge is made, as it was in this case, for "taking" a photograph, in law that must include property in the negative. Against this will be argued, no doubt, the "customs of trade" and "usages of business," both of which, as we explained when writing on this same subject in our volume for 1879, are nearly, if not quite, as binding as the law itself.

Is a negative a photograph? In the eyes of a photographer, and literally, it is; but in the eye of the public it is not. To them a photograph is the picture itself, and not the plate from which it is produced. Indeed, many of the general public are not even aware that a negative is necessary at all for the production of their photographs, and it really is not with some processes.

The custom of the trade with regard to a photographer and his *clientèle* is consistent with all his dealings in every branch of the profession. If he send a negative to have a number of Woodburytypes made from it, he does not expect to get the gelatine relief and the lead matrix from which the impressions are produced. Nor does he, in the event of his ordering a number of collotypes, expect to receive with them the plate from which they are printed. Again: if a photographer send a negative to have an enlargement from it, either in carbon or platinotype, he does not consider himself entitled to the transparency and the enlarged negative as well as the print. But all these should become his property if anyone who gives him a commission to take a photograph is entitled to the negative as well.

In the event of the appeal being prosecuted, and its being decided that the negative is not the property of the photographer, he will be awkwardly placed in many ways beyond its loss. In the event of his receiving a commission for (say) a carbon enlargement he would not only supply the enlargement and have to deliver up his original negative, but he would also be compelled to hand over as well the transparency and enlarged negative, to neither of which, according to the custom of the trade, is he at present entitled, supposing he has put the enlargement out to be made. With most houses that make carbon enlargements it is a rule—and a recognised one, too—not to part with the transparencies under any conditions whatever; indeed, they almost look upon a transparency as a "trade secret," although they permit the purchase of the enlarged negative.

In the projected new Copyright Bill, which has been before Parliament now for several years past, the ownership of the negative is provided for (or at least implied), there being a clause which stipulates that all negatives executed for a consideration are not, under a heavy penalty, to be used except to the order of those for whom they were produced. If this bill ever become law the ownership of the negative will then be established. In the meantime, and pending the appeal (if it ever come off) in the case previously referred to, we suggest to our readers the advisability of abstaining from making a definite charge for taking the negative, or it may happen that if the point were again contested the legal meaning of the term "photographing" may not be interpreted in the same sense as it was by the judge of the Swansea County Court. In making the charge it should be simply for so many photographs, or (say) a photograph and so many copies. In no case should the term "negative" be mentioned, or, indeed, "taking" a photograph.

From the communications which have been received by us of late it appears that the Swansea case is by no means an isolated one, and that a certain portion of the public do at present consider themselves legitimately entitled to the negative. To dispel this idea our correspondents will do well to bring the decision recently given respectfully under their clients' notice. By so doing they may possibly avoid litigation, which, in all instances, it is very desirable to do between a photographer and his customers.

THE DECANTATION OF LIQUIDS.

In our contemporary *La Nature*, of last week, is figured a very simple and effective arrangement for pouring from large carboys the whole of their contents, even to the last drop, with ease and safety, which we may with advantage describe to our readers. Of all the simple operations of the dark room or laboratory there is none which shows the trained worker more readily than the mode in which he takes up a bottle and pours out a portion of its contents; and when he handles a large carboy in which corrosive acids—nitric, sulphuric, &c., not to speak of acetic acid and other more innocent liquids—are stored, he does it with safety if not with ease.

When, however, the inexperienced hand attempts (say) to draw off a pint or two of acid from one of these cumbrous vessels he does it at great risk of spilling its contents, and runs a considerable chance of blinding himself by returning the vessel to a perpendicular position so quickly as to cause it to spirt or splash out. The *vide-tourie*, or carboy-pourer, of M. Serrin (the inventor of the electric lamp that bears his name) obviates these and other difficulties, and renders the pouring from carboys a matter of ease and safety when the act is performed by a single workman without aid. It is so simple that the wonder is it was not invented before, and it may be described without the aid of a diagram.

It consists, in effect, of a base or platform to hold the carboy, a couple of uprights at its back, and attached to each of these uprights a construction exactly like the half of a small wheel cut through its diameter. The two semicircles are directed outwards, and when the structure is tilted forwards the carboy follows suit, the whole rocking to and fro upon the wheels with great ease; thus any inclination, even to turning it upside down, is given without jerk or splash and with perfect ease. The apparatus seems so simple and useful that we consider we are doing its inventor justice in bringing it before the notice of our readers, many of whom, no doubt, have experienced the difficulties and dangers of carboy-pouring.

Pouring from a carboy, however, is by no means the only operation of the kind in which a little knowledge may be imparted with advantage, and, indeed, for the pouring itself, in some cases, syphoning may be substituted. When corrosive liquids are decanted by a syphon one with a double limb is best employed, and the limb filled, not by suction with the mouth, but by exhaustion with an india-rubber ball. Where a syphon of this kind is required a very useful home-made one can be constructed out of any round bottle and a large cork or bung. The bottom of the bottle is cut off by any of the well-known methods, and its place taken by a large cork, in which two holes have been bored—one for the insertion of the end of the syphon, and the other for an extra tube which should extend a little higher than the bend of the syphon. Placing the finger (protected, if necessary, by an india-rubber stall) upon the neck of the bottle, the air may be exhausted by the extra tube, and the liquid, thus brought into the syphon, caused to flow through the bottle upon removing the finger.

Another form of syphon useful for general purposes is made by blowing a bulb near the end of the long limb, which holds sufficient liquid to keep up the flow when the short limb is immersed quite empty into the liquid to be decanted, till both tubes are full and a complete flow is established. We are inclined to believe that one reason why a syphon is so little seen in the photographer's laboratory is the difficulty experienced in "setting it to work"—a difficulty quite obviated by making it in this form or buying it so made.

But, really, for photographic use a syphon in ninety-nine cases out of a hundred is used for decanting liquids from a bottle, and then, mainly, for one or two particular liquids—collodion or varnish. By far the simplest method to employ is to keep the syphon permanently fitted with a cork and blow-tube on the shorter limb. A very well-tapered cork should be selected, and two holes bored into it—one for the syphon leg and the other for a small extra tube slightly bent. This latter tube should fit tightly, but the syphon tube only just sufficiently so to allow it to slide stiffly in and out of the cork. Then, if each syphon be kept for one especial purpose, this little arrangement will be found particularly useful. All that is required to set the syphon flowing is to insert the short limb in the bottle, the cork being adjusted at such a height as to allow the limb to be clear of the bottom; then, applying the lips to the small tube, a slight puff of air through it will force the liquid into the syphon, whence it will flow until either the bottle be empty or the instrument withdrawn. The only difficulty that could arise with the apparatus so arranged would be when the cork would not fit into the bottle it was desired to empty; but this drawback, which would be little likely to occur with a well-selected cork, could be easily overcome by placing the cork, if too large, upon the mouth of the bottle and pressing strongly while blowing, or, if the cork were too small, wrapping a few folds of paper round it till it fitted. Where small quantities only at a time were wanted a plan might be adopted like that we have seen in one dark room. The syphon was replaced by a bent tube with a short limb outside, and the liquid would only flow as long as the blowing was kept up. By this means an exact quantity could be drawn off and no trouble caused by the presence of the small quantity contained in the syphon when its action was stopped by withdrawal from the liquid.

We have more than once been amused by the mishaps of an inexperienced hand, after spending much time in boiling a bath to clear it of ether, &c., or, evaporating down a solution required in a more concentrated form, in pouring the liquid from the evaporating dish into another vessel. The first time this is done there is generally a spill; yet if the operator had but placed a glass rod against the lip of the dish and poured gently he would not have spilled any of its contents, and the liquid would have flowed precisely where he desired.

Sometimes a liquid is perforce contained in an awkward-shaped vessel from which, through being provided with no proper lip or spout, it is next to impossible to pour; if the edge be very slightly greased at one part the regular flow of the liquid will be greatly facilitated. We will conclude by alluding to the mode of pouring out of a bottle, which simple operation is usually performed in the most slovenly manner, with the result of a loss of neatness and cleanliness that might well be avoided.

Firstly, stoppered bottles are decidedly best where the liquid is in frequent request; secondly, the stopper should be withdrawn by the third and fourth fingers of the left hand, the thumb and forefinger holding the measure; thirdly, the bottle should be held so that the pouring is away from the label, which thus need never be stained if a drop should run down the sides; and, fourthly, to prevent as much as possible any drop running down and so soiling the bottle and the hands the next time it is handled, the lip of the bottle should be just touched with the lower part of the stopper before replacing it. The drop just hanging ready to run down will be taken up in the stopper and returned to the bottle. These instructions may seem intricate to read, but they are not so in practice; indeed, they indicate not only the best but the quickest mode of performing the simple act of pouring out of a bottle. Stress is laid upon it from the idea we hold that neatness of manipulation aids in improving the quality of the work, and in the comfort and ease of all details concerned in carrying it out.

AMONG the scientific *Transactions* of the Royal Dublin Society, recently issued, we find an account of an equatorial telescope of new form by Mr. Howard Grubb, F.R.S., which will greatly facilitate stellar observation. It is constructed, optically, on the dialytic principle, the mechanical arrangements being such that the light, after passing through the dialyte, falls upon a plane mirror and is reflected up through a stationary tube (containing the eyepiece) pointing towards the mirror, and the eyepiece end of which is introduced into the room, in which the observer sits at his ease. The slope of the tube, *down* which he looks at the heavenly bodies, is similar in degree to that at which a microscope is placed when the microscopist has got it comfortably arranged to inspect the minute objects in nature.

WE have received from the Rev. T. E. Espin, Director of the Observatory of the Liverpool Astronomical Society, a photograph of the cluster of stars round (Alpha) Persei, which is a most successful piece of stellar photography. The exposure given was one hour, the instrument used being the equatorial stellar camera, which forms an important item in the equipment of the West Kirby Observatory, and which has already done good work. The perfection of the mechanism and the accuracy of its timing are shown by the sharpness with which the large number of stars of varying magnitudes are rendered, there being an entire absence of the oval or egg-shaped distortion so commonly seen in stellar photographs. The picture, which is of quarter-plate size, is, except in the importance of the subject, quite as interesting as Mr. Common's famous *Nebula in Orion*, and Mr. Espin is to be congratulated on his success.

WE are much pleased to learn that arrangements are being made to establish a photographic society in Nottingham, to be designated the "Nottingham and Provincial Photographic Association." We trust that all success will attend the efforts of the founders.

IN our issue of March 7th, the Rev. H. B. Hare called attention to a peculiar example of green fog which had come under his notice, and some of the negatives to which he referred have since been submitted to us. The opinion expressed by the photographer by whom the pictures were taken was that the green fog was absent from "the portion about the middle on which the plate rested on the pneumatic holder while they were being coated." But this is, we think, from an examination of the negatives, scarcely a true explanation of the clear patch which certainly appears near the centre of each plate. From other markings we should judge that dirty glass is the cause of the green fog, and that the fog-inducing matter, whatever it may be, has been cleared away from that part of the plate upon which the emulsion was poured in coating. The transparent patches are not large enough, nor are they sufficiently regular in form, to be caused by the pneumatic holder. If we had information that a substratum of any sort had been applied to the glass before coating with emulsion, we should not have the least hesitation in connecting that with the result; but present appearances decidedly favour the theory of badly-cleaned plates, as the marks of the polishing-cloth are clearly visible in more than one case.

As an instance of the use of photography in illustrated journalism, we may mention that Mr. W. H. Harrison's pictures, in the last number of the *Graphic*, of the Carnival at Lucerne were chiefly founded upon his photographs.

A FRIENDLY recognition of the services rendered to photographers in New York and neighbourhood by Mr. T. C. Roche, the photographic demonstrator at Messrs. E. and H. T. Anthony and Co.'s, Broadway, New York, was made on the 18th ult., when a large number of photographers met together under the presidency of Colonel Wilcox, the junior member of the firm named. After dinner a handsome gold watch and chain were presented to Mr. Roche, who made a fitting response. Speeches on various topics connected with the art followed. From all that has come to our knowledge respecting Mr. Roche, this recognition of his valued services to photography is richly deserved.

OUR readers will be interested to learn that the first public exhibition of the results of the French expedition to observe the eclipse of last year was made on the 10th ultimo, M. Janssen having delivered an address to the Alpine Club on that day, and illustrated his discourse by magic lantern projections of the photographs obtained.

THE exhibition of thermometers, illustrated also with photographs, &c., to which we have already alluded, was opened to the Fellows of the Metereological Society and their friends on the 19th ultimo, and was of a most interesting character. There were one hundred and thirty-six exhibits. At the monthly meeting of the Society, held the same evening, the President gave an interesting paper on the history of thermometers, from which it appears that the actual inventor of the instrument is really unknown. He stated that most of the improvements in the instrument had been made by Englishmen. The freezing-point was the suggestion of Robert Hooke, and the boiling-point of Halley, who also first suggested the use of mercury instead of spirit. Fahrenheit, though a German by birth, was a *protégé* of James I., and died in England. Réaumur's thermometer owed its origion to De Luc, while the centigrade thermometer, usually credited to Celsius, was really invented by Linnæus.

IN the revision of the atomic weights by Mr. F. Wigglesworth Clarke, S.B—to which we have alluded on a previous occasion, and the results of which are in course of publication—he states that an experimental revision of the weight of gold is very desirable, as it is a metal which can be readily applied to the determination of the atomic weights of other elements. He gives as the result of his revision a mean of 196·155, with a possible error of *plus* or *minus* ·095. When, however, it is noted that Berzelius obtained 196·186 in one set of experiments and 195·303 in another, while Luvol (the only other experimentalist whom Mr. Clarke considers worthy of consideration) obtained 195·794, it may be readily seen how desirable such revision really is.

It will be noticed that, taking the difference between the highest and the lowest of these readings, we find, on a basis of arithmetical calculation, a difference of about threepence an ounce in the estimated price of chloride of gold.

The question as to the usefulness of photographic guns and revolvers for the amateur photographer is, for the present, solved by the manufacturers; they make them and must endeavour to sell them. That they are likely to attain a certain popularity seems probable; for we see in our foreign contemporary, *La Nature*, a capital illustration of a photographic revolver just invented (it states) by M. Enjalbert. The apparatus is ingenious enough, and for taking "pot shots" is, under certain conditions, likely to be very useful. The barrel of the pistol forms the sliding tube for holding the lenses, and the revolving chamber contains a dozen dry plates, necessarily of diminutive size—about three-quarters of an inch in diameter. The arrangement for exposing and changing the plates is very ingenious and apparently serviceable. A pull of the trigger opens and closes the shutter, giving what is estimated to be the one-fiftieth of a second's exposure. A turn of the revolving-chamber by the hand removes the exposed plate, and substitutes a fresh one ready for the next "shot." The whole instrument forms a compact and ingenious apparatus. But the doubt of the usefulness, except under limited conditions, of any such apparatus still remains; indeed, the editor of *La Nature* seems to see this difficulty himself, for he says—"The photo.-revolver only offers one inconvenience: in certain cases it may be particularly terrifying to those at whom it is pointed. It is easy to avoid this inconvenience by covering the apparatus with a handkerchief or veil, and so hide its alarming aspect." As a matter of fact, we find it difficult to see what could be done with such an instrument by an amateur. In a crowded street he might be roughly handled, or, during the prevalence of such outrages as have of late so alarmed the public, might meet with unpleasant attentions from the police; while, if he attempted to secure single studies, the probability is he might find that his target could hit straight out from the shoulder. The latter, we consider, would be a contingency as probable as justifiable, from its similarity to the foolish and dangerous practice of pointing firearms in joke at any one sufficiently near to be alarmed—a practice that has led to the sacrifice of many a useful life, followed by a lifetime of self-reproach consequent on the unintentional homicide. For this reason we would far rather see a similar amount of skill and ingenuity expended upon a more innocent-looking form of apparatus.

SULPHITE OF SODA IN THE ALKALINE DEVELOPER.

Some discussion seems to have arisen lately in these columns as to the use of the sulphite of soda in the alkaline pyro. developer; and, as I have used it with success and to my complete satisfaction for a considerable time—in fact, since first it came into notice—I venture to make a few remarks concerning my experience of it. In discussing the merits of a process or of a material of any kind the question of who first invented, originated, or introduced it has but little bearing on the real issue; but in the present case I have no hesitation in saying that I never heard of sodic sulphite, much less of its use as an ingredient in an alkaline developer, until I first noticed, or heard of, Mr. H. B. Berkeley's recommendation of it in conjunction with the pyrogallol used in the ordinary development of gelatino-bromide plates.

There can be little doubt that pyrogallic acid—an extremely light substance and very easily blown about a room—is a dangerous article where sensitive plates are being used. It is also pretty certain that, while weighing a few grains of this light material is a great nuisance, guessing at the requisite quantity for a plate is an operation at once risky, inaccurate, and indicative of laziness. A freshly-opened bottle of pyro. is a very different affair to gauge by the eye from a bottle that has been open for some time; and one grain of pyro. more or less in an ounce of developer makes a serious difference in the qualities of a negative. Many a plate I have all but spoiled for want, or by excess, of a grain or two of pyro. For these reasons I deprecate what I must admit was at one time my own practice—the guessing at the quantity of pyro. used in the development of a plate. We must then fall back on a solution of pyro. in some proportion or other. Solutions of the reagent in question may certainly be made at the time and in the quantity required, but, as I said before, pyro. is not a nice substance to weigh more frequently than necessary. I never, when I can help it, use grain weights, and if a larger quantity be required (say fifty grains) the pans of an ordinary chemical balance are too small to carry such a bulk, and the flaky and expensive pyro. falls or is even wafted about the room. It remains, therefore, to make up a solution of pyrogallol more or less concentrated. But here arise other troubles consequent upon the nature of pyro. It rapidly oxidises, becomes coloured, and loses its reacting powers. Various have been the methods recommended and adopted to prevent this discolouration and loss of power, and to a few of these expedients I must now allude.

Not having at hand a file of The British Journal of Photography I cannot guarantee that I shall give the various means used to preserve the pyro. in their chronological order. I shall take them as they occur to my memory. First, I recollect some person recommending and myself using a small quantity of citric acid added to the solution of pyro.; but I also remember that even with this addition strong solutions of pyro. kept only a short time in good condition, while weak solutions, though keeping the pyro. colourless by itself, immediately ceased their good offices when the ammonia was added to the pyro. to make the alkaline developer, and at the end of the operation of developing a landscape negative the plate was densely black either by transmitted or reflected light. As a result of this staining it was impossible to tell accurately what stage the development had reached; and, further, as a rule the negative when fixed was so stained as to require "clearing" with alum and acid to a very considerable degree. More than all this, the presence of acid in the pyro. solution inculcated an extra amount of ammonia to render the developer sufficiently alkaline to help the pyro. in its duty of reduction. With sulpho.-pyrogallol this last objection does, I admit, appear to hold good also, but to a much less extent, according to my experience.

Another custom I remember was that of making a strong solution of the pyro. in strong or even absolute alcohol. This kept the pyro. in good order so long as there was no ammonia present, but on the addition of ammonia the same drawback appeared as in the citric acid case—the complete staining of both solution and film—and, what was quite as serious, the plate required far more washing after development. Anyone who has travelled and developed negatives *en route* as I have understands the frequent trouble consequent upon a necessity for prolonged washing at any stage of the proceedings.

Then we had the pyro. dissolved with alcohol and glycerine. I used this (Mr. Edwards's) system for a long time, and, indeed, stuck to it till what I considered, and still consider, a better method became known. *Why* the glycerine preserved the pyro. I never discovered; but it did preserve it fairly well for a long time. The glycerine, however, like the alcohol, entailed a washing—not, perhaps, formidable with a tap of water at home, but a nuisance for tent work, and a marked impediment in certain places, among which I may instance Venice.

I do not remember how I first came to use Mr. H. B. Berkeley's sodic sulphite formula, but since I began to work it I have never ceased to make it my standard developer. There have been times when I rejected it in the development of instantaneous negatives, because I had an idea that under-exposed plates gave more detail without its use; but I have long since recanted, and I am now aware that the appearances which led me to suspect it of retarding or impeding development were completely deceptive. In fact, if I did not habitually use sulpho.-pyrogallol for development I should use it for rapidly-exposed plates, for the simple reason that under prolonged development the plates will not stain with sulpho.-pyrogallol, while without it they would be very seriously stained.

The commonest indictment against sulpho.-pyrogallol is that it "slows development." I am not quite certain that it does prolong the operation; but admitting that it does—it can only be slightly—I deny that it in any way *prevents* it. I mean to say that all detail and density obtainable by any other method can be obtained with sulpho-pyro. The fact is the opponents of sulpho.-pyrogallol have mistaken its best quality for a great disadvantage. The point of all others that I like about the sulphite is that under its influence details and shadows remain to the very climax of development fairly visible, while with all the other processes the details and shadows—especially in landscape negatives—are all but homogeneous in appearance before the development can be called complete. I have always been an advocate for close examination of the progress of development. I like to see the gradual and subtle changes taking place all over the plate. With sulpho.-pyrogallol my wishes are fulfilled; with other developers I may stare my eyes out of my head at what seems a black curtain being drawn over the stage on which I wish and require to study the figures. This, then, I submit to be the prime advantage of sulpho.-pyrogallol in the developer—even on a fully-developed plate I can examine *almost* every detail. Other preservatives of pyro. may—though I think they do not—rival sulphite in their preserving powers of pyro. without ammonia, but once mix ammonia with them and staining starts and proceeds to "outer darkness."

This fact entails another advantage of some consequence to the impecunious or lazy: the same solution of sulpho.-pyrogallol will develope negative after negative. The ammonia may be reinforced from time to time, but the solution will keep wonderfully clear for I don't know how long. I have now some sulpho.-pyrogallol solution that developed three plates at least eighteen months ago, and it is clearer than an ordinary pyrogallol solution ten minutes after ammonia has been added. Those who allege that sulphite slows development ought to remember that development must not reach *apparently* the same stage with the sulphite as without it.

A cry I frequently hear, but never yet understood, is—"the appearance of a wet plate." This similarity to a wet plate probably consists in the colour of the metallic deposit constituting the image in a negative; sulpho.-pyrogallol produces this similarity to a marked degree. What I consider *the* greatest defect in gelatino-bromide plates is want of detail in the high lights, which is mainly due to the dense black colour of the deposit in these high lights. This density is partially obviated by the use of sulpho.-pyrogallol, and hence arises one similarity to a good feature of wet-plate negatives. But the weak point of collodion negatives and the strong point of gelatine ones is certainly detail in the shadows, and, in this matter, plates developed with sulpho.-pyrogallol do certainly not resemble wet plates. My favourite developer answers the cry I have mentioned so far as it ought, but fails to apply to the undesirable qualities of the vaunted collodion.

I have said that a sulpho.-pyrogallol solution *plus* ammonia having developed three plates has kept well for eighteen months, so I need not say that its keeping qualities are almost infinite when isolated from temptations to go astray from the path of purity. Sulpho.-pyrogallol, whether bought from the originator or made by myself, keeps far better than any other solution I ever made or saw.

I care nothing in what proportions a person keeps his chemicals dissolved, provided he knows precisely what his proportions are, and has to extract a required quantity of the chemical in solution; but I cannot suggest a more convenient proportion than the ten-per-cent. solution recommended by Mr. Berkeley. For that reason I prepare any solution exactly in those proportions. I can conceive nothing more easy to remember or more simple to act upon than "ten drops equal one grain."

Lately I have been repeatedly asked to give my formula for the preparation of this sulpho.-pyrogallol. It is simply Mr. Berkeley's formula, which can be found in the last ALMANAC, and I never gave a formula with greater pleasure or more confidence; when once fairly tried it will be constantly used. I take four ounces of sodic sulphite, and I "see that I get it." It is a white crystal, and when washed leaves a very nasty sulphurous taste on the palate for a long time. It can be purchased for sixpence per pound, but I will not answer for it. I always use Hopkin and Williams's at two shillings per pound. The four ounces I dissolve in about six ounces of water. I am told Mr. Berkeley does not like the water to be hot; I make mine boil and find no harm. In a test tube I make about three drachms of saturated citric acid solution also hot, and I pour into the sulphite solution about a drachm of the citric acid solution to begin with. I then stir well and test with *good* test papers—one red and the other dark blue. (Pale blue is not to be trusted.) I add, by about twenty to ten drops at a time, citric acid until, first, alkalinity disappears, and then a slight acid reaction on the good litmus-paper appears. The solution must be very thoroughly stirred after each addition of acid, and, finally, the whole solution must be distinctly, but not largely, acid. The success of the operation depends on the solution being acid. If too acid it neutralises the ammonia in development; if alkaline the whole, or a great part, of the advantage is lost. When cold I again test, and if correct, I make up to ten ounces, pour the lot into a bottle of pyro., filter, &c., and the operation is complete. Label "Sulpho.-pyrogallol, ten drops = 1 grain pyro." Date your label, and, keeping a little of your solution, examine your sulpho.-pyrogallol a year from date, and "report progress." If you are satisfied, thank Mr. Berkeley and not the writer.

ANDREW PRINGLE.

STANNOTYPE.

No. IX.

WE have now arrived at the stage at which the relief, so far as its photographic manipulations are concerned, may be considered as finished, the only remaining operations being the removal of chance defects and the facing with tinfoil to fit the mould for printing purposes. Neither of these operations should be attempted until, as directed in the last chapter, the relief has been completely desiccated.

The process of removing defects from the relief or retouching is a very simple one, and the results attainable by its means are of a character unattainable by any other method. For instance: a cracked, broken, or badly-scratched negative may be made to yield prints in which the faults of the negative are absolutely undetectable, and this in the simplest manner possible. It consists, briefly, in removing, by a sort of planing process, the inequalities in the relief which represent the defects. This is effected by means of a strip of glass about half-an-inch wide, with a clean cut fracture, which is applied at a very oblique angle with a half-cutting, half-scraping, action to the parts to be removed.

This method is clearly only applicable to one class of defects, namely, such as are in *relief* in the stannotype mould, and would appear white in the print. It is, therefore, necessary to make special preparation of a negative which contains blemishes both of a transparent and opaque character. The former must, in fact, be converted into the latter by painting out in the negative so as to be represented as white or transparent markings in the intermediate transparency. The opaque defects, such as spots or stains, require no treatment at this stage.

Let us take as an example a broken negative which is also badly scratched. The example we have in view is one actually shown to us by Mr. Woodbury. The broken pieces are first of all placed together and cemented to an extra glass, the junction being painted over with opaque colour to form an even line free from irregularities caused by diffraction from the broken edges. In the same manner the scratches are also carefully gone over in order to render them opaque. The positive produced from such a negative presents anything but a sightly appearance; however, that is of little consequence. The relief represents all the defects as black lines, which, by means of the strip of glass, are gradually planed down to the general level.

Until this operation has been witnessed the ease and certainty with which it is performed and also the rapidity are incredible, and the results are such as it would be practically impossible to attain with any amount of care and skill by other means. The negative to which we have referred above is one many years' old, which has apparently been knocked about amongst dirty glass until it had become apparently hopelessly scratched and finally broken; and yet the prints show no vestige of a defect of any sort. This is an extreme case, that would probably not be mastered on a first or second attempt; but very little practice will enable the careful operator to treat any ordinary cases with perfect success.

It may be asked—Why go to the trouble of blocking out transparent defects in the negative, when, if left alone, they might be removed from the *transparency* in the same manner as opaque ones from the relief? The reason is that, though the removal of the defects from the transparency is perfectly easy so far as the *relief* is concerned, yet the abrasion of the surface leaves the gelatine partially opaque, and in printing the blemishes are reproduced with all the force of the original. This semi-opacity is, of course, present under similar conditions in the relief, where, however, it is of no consequence whatever.

The defects having been carefully removed, it only now remains to "surface" the mould, which is effected by cementing to it in intimate contact a sheet of tinfoil. The first step towards this end consists in applying a thin coating of adhesive material to cause the tinfoil to adhere to the gelatine surface. Supposing the relief itself to be perfectly sharp—that is to say, to possess the greatest degree of sharpness it is possible to secure—it will be plain that every addition to its original surface, whether of varnish or tinfoil, must necessarily detract more or less from that perfection of minuteness in detail. Hence it is important that the film of adhesive material be as thin as possible.

The best material for the purpose is pure india-rubber dissolved in chloroform to the strength of about one or two grains to the ounce. Chloroform makes a better solvent than benzole; it dries more rapidly, gives greater adhesion, and is more likely to be free from grease. This solution is applied to the plate in the same manner as collodion, the surplus being returned to a separate bottle to be filtered before again being used. The plate is then set on one side for ten minutes or a-quarter of an hour, or until it has become quite dry and only presents the slightest possible "tackiness," like a newly-cut surface of india-rubber. A brush dipped in a much stronger solution of india-rubber is then passed round the edges as an extra safeguard, and the mould is ready for the tinfoil.

This must be perfectly smooth and free from holes, and should be as thin as possible consistently with the amount of usage the surface will have to undergo. As has been pointed out, every interference with the original surface of the mould reduces its sharpness to some extent, and, clearly, the thicker the tinfoil the greater must be the loss of sharpness. Where, therefore, but a few prints are required, a thin tinfoil may be used; but when a larger number are wanted a stouter and more durable surface must be provided. Tinfoil faced with steel is supplied for this purpose, and possesses far greater durability in proportion to its thickness than tinfoil alone.

The foil, having been cut to the size of the relief, is smoothed out on a sheet of glass by means of a pad of velvet on a soft hat brush. Examine it against the light in order to be assured that there are no flaws or holes in it. These, by admitting moisture from the ink in printing, would produce white marks in the print from swelling of the gelatine relief.

In order to secure perfect contact between the tinfoil and the gelatine surface a considerable degree of pressure is necessary. The best method of securing this is by means of an ordinary domestic wringing-machine with rubber rollers, which, with slight modification, answers every requirement. The modification necessary consists in an arrangement by which the rollers can be drawn apart so as to admit of the relief, with the tinfoil in contact, being passed in between them without touching. The rollers are then brought together in the centre of the plate, and, suitable pressure having been applied by means of the screw, a backwards and forwards motion of the rollers is given, extending gradually from the centre of the plate to the edges. In this manner all air is driven out from between the tinfoil and the relief, and the most perfect contact secured.

Where the double-roller arrangement is not available, a hand-roller, like a printers' inking-roller, may be used as a substitute, but the results are not so good. Direct pressure in a screw press with a sheet of soft india-rubber and a thickness or two of felt laid over the tinfoil also answers tolerably well; but the double-roller is both simpler and more perfect in its results.

After leaving the surfacing machine the relief is ready for printing from, which operation will be dealt with in another chapter.

ILLUMINATION OF THE DARK ROOM, AND SOME OPTICAL EXPERIMENTS.

[A communication to the Photographic Society of Great Britain.]

In turning over some old specifications of patents I came across one by Claudet, in 1844, in part of which he says:—"The fifth and last improvement consists in performing all the operations (of taking a daguerreotype) upon the plates, which were formerly carried out in the dark—now in a room lighted through media of various colours; but red I prefer, which, having very little effect upon the plates covered with the sensitive coating, allows the operator to see how to perform the work without being obliged, as before, to remain in a dark room." I suppose, then, we may conclude Claudet was the first to use any light whatever in the early days of photography. Forty years later we still had the subject of illuminating the dark room occupying our attention, though I had thought that the question as to which light was the best and safest had been pretty well settled. The subject of the canary medium has, however, revived; and, like others, I have examined its qualities.

At the January monthly technical meeting of the Society I brought some samples of what I supposed to be canary medium, and showed the results I had obtained with it. The canary medium that I had manufactured was made by emulsifying chromate of lead in gelatine by means of the double decomposition of acetate of lead and bichromate of potash, and applying it to glass and paper. I also soaked paper in acetate of lead and then in bichromate of potash, and got a very good imitation of the canary medium. The results were not satisfactory. With three gelatinised glasses in front of the negative, in three and a-half minutes I was able to obtain a fully-exposed transparency, whilst, with the paper in a lantern, two thicknesses of same paper impregnated with the lead chromate enabled me to get a transparency in three minutes, the source of light in the lantern being a candle and the negative placed a foot from it. The illumination was brilliant—much more so than when I used the common orange packing-paper, which I show. With the orange paper, after five minutes' exposure, I got the very faintest trace of an image.

So far, then, my test went to prove the superiority of the orange paper. After I had made my remarks at our monthly technical meeting, Messrs. Scorah and Co., of Bradford, kindly sent me a sample of the true canary medium, and with this I have experimented. The paper you will notice is thick—I may say very thick—much thicker, indeed, than the orange paper. Now, about the illuminating value of the two:—I show a lantern in which we have one side formed of a square of canary medium, another of a square of orange paper, and the third side a square of stained red glass, of which I shall have to speak by-and-by. I think that the members of the Society will agree with me in saying that of the two paper panes the orange is the more brilliant. Now, appearances may be deceptive, of course; so, to avoid all cavil, I made photometric tests of the two. The candle being lighted, a piece of printed matter was held in a vertical plane. The eye was kept at a fixed distance from the paper and the lantern moved till the letters of the words could not be distinguished. In the case of the canary medium I found that at two feet and a-half inch the letters first became confused, whilst at two feet six and a-half inches they became confused when the orange light was tested. Though not absolutely exact, the relative intensities of illumination may be taken as the squares of the distances, which would make them about as sixteen to twenty-five, or the orange paper had one and a-half times as much illuminating power as the canary medium. Testing the stained red glass, I found that the light had to be moved to four feet four inches distance, or was four and a-half times more luminous than the canary medium. Thus, the illuminating values of the three were about as follow:—

Canary.	Orange paper.	Stained red.
1	1½	4½

To further test this matter, closely-ruled black lines, on a white ground, about one-fiftieth of an inch apart, were taken and placed at six feet distance from a small observing telescope, and the lights moved as before. In the case of the canary medium the lamp had to be moved three feet two inches from the ruling, the orange four feet one inch, and the stained red six feet seven inches. These were all the mean and three closely-accordant readings. This gave the relative illuminations as—

Canary.	Orange paper.	Stained red glass.
1	1·63	4·32

The reading test and the more accurate test, here adopted, are closely accordant in every way. In fact, this is very much the plan that is adopted for star magnitudes, though in this case the surface of the object-glass is diminished by diaphragms, instead of the stars themselves being deprived of luminosity.

So much for my own readings. It seemed that it would be curious to note any differences in individual eyesight as to the intensity of colour in these media, and yesterday I had the good fortune to secure Mr. C. Ray Woods as an observer, and later Mr. Cadett. In this case the experiment had to be slightly varied, from my dark room being only partially available, and the light and the eye were kept in a constant position, whilst the ruled lines above mentioned were moved to and from the observer. The following table gives the result of the comparison of Mr. Woods's eyesight for colour with that of my own:—

	Mr. Woods.			Captain Abney.		
	First Experi.	Second Experi.	Mean.	First Experi.	Second Experi.	Mean.
Canary paper ..	1·00	1·00	1·00	1·00	1·00	1·00
Orange paper ..	1·87	1·86	1·86	1·51	1·44	1·47
Stained red glass..	5·14	4·76	4·90	3·00	3·12	3·06

To sum up: Mr. Woods made the illuminating powers 1, 1·86, and 4·90; whilst I made mine 1, 1·47, and 3·06. It will thus be seen that as the green was cut off, so Mr. Woods's vision became more acute than mine.

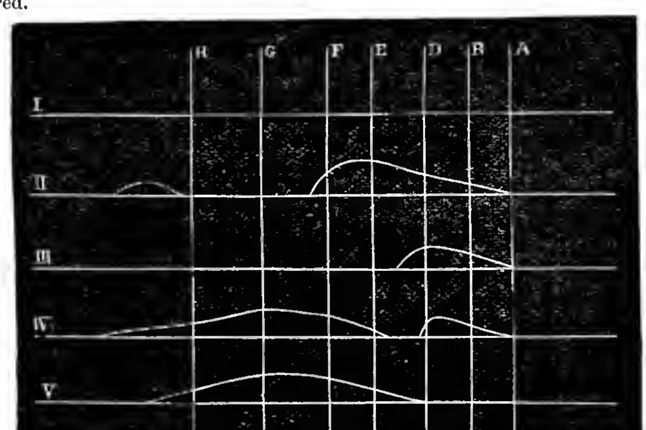
Mr. Cadett's figures were again different to mine; and here I must interpolate that I have never met with a more exact observer. His observations did not vary more than a-quarter of an inch on each side of the mean. His reduced readings were 1, 1·39, and 2·70. We see, therefore, that his eyes are less susceptible to red rays than mine, and still less so than Mr. Woods's. This last method of testing is inexact, of course, and cannot be compared for accuracy with that of the fixed lines and telescope, and apparently the results do not accord. I think, however, it will be seen that the want of accordance is more apparent than real. Taking my own observations of printed matter for instance: when the printed matter was moved, the distances, in the last experiments, from the eye (not from the light) were twenty-one inches, twenty-four inches, and thirty inches.

The angles subtended by the writing at the three distances would be inversely as the distance, and the confusion of lines would be sooner arrived at than if they always subtended the same angle, as was the case in the first experiment. To make the two readings comparable one with the other—the orange paper and stained glass readings—the last experiments must be multiplied by $\frac{34}{21}$ and $\frac{90}{21}$ respectively. This would give the reduced readings as 1, 1·63, and 4·37, which is very nearly the same as 1, 1·69, and 4·32, which were the figures of the telescope reading. However, one thing has been apparently proved—that the eyes of three persons chosen at random are not equally sensitive to the red rays. Mr. Woods informs me that he can scarcely see H and K in the extreme violet limit of the spectrum; whilst I can see not only H and K, but L, and, in bright light, M as well. It seems then as if there were in his case a general lowering of sensibility and wave-length. I have not taken into account colour-blind people. This I may deal with at some subsequent period.

I may remark that with a sheet of white tissue paper in front of the glass the figures came out as—

Canary.	Orange.	Stained red, with tissue.	Stained red, bare.
1	1·63	2·93	4·37

By means of the pocket spectroscope it was possible, by placing two pieces of paper alongside one another in the lantern, to examine their absorption spectra comparatively. The result showed that the red and yellow of the canary medium were decidedly fainter than in the orange paper, whilst in the former appeared more green and a little blue. *Primâ facie*, then, the orange should be the best medium to use for photographic purposes. So far, we have had merely a theoretical test for the chemical value; the question is, what is the practical one? A plate was exposed behind a negative with a piece of orange paper across one half, and a piece of canary medium across the other, with the result that, after one and a-half minute's exposure to candle power two feet off, there were traces of an image through both, the two being nearly alike. Perhaps the orange paper had a little the best of it. Behind the stained red glass not a trace of an image appeared with the same exposure. Thus, then, the practical test leads to this conclusion, namely, that of the three media stained red glass is the best, both as for illumination and want of effect on a plate, whilst the canary and orange papers acted alike as to their effect on the plate; but the illumination was fifty per cent. in favour of the latter. I must confess that the canary medium behaved much better than I expected in candle-light. I may add that with daylight it is not such a good protection as the orange paper. Stained red glass behaves better than either of these two; and when I say stained red, I do not mean orange or flashed silver glass, which is often spoken of as stained red.



Ultra-violet Violet Blue. Green. Orange. Red. Ultra-red.

I have to lay before the meeting a photograph of the absorption spectra of different glasses, taken by the electric light. The first plate shows—

1. Chromate of lead.
2. Orange glass.
3. Stained red.
4. Flashed ruby.
5. Green glass.
6. Green glass and chromate.
7. Green glass and ruby.

Another plate I show is the same as the first, with the exception that it was taken with a candle as the source of illumination, and that in No. 4 a very deep ruby flashed on two sides was used, and for No. 7 cobalt glass and ruby superposed were spectroscoped.

The orange glass lets through the ultra-violet with the electric light, but does not do so with the candle, as there are few ultra-violet rays in its light. The ruby glass lets through the green and blue in both cases. In the second plate the impression made by these colours is only faint, but still it is there; and when it is recollected that the two minutes' exposure was given to a slice of light $\frac{1}{200}$ inch broad, spread out into a spectrum four inches long, and that an impression was made by it on a seositive plate, it will readily be seen that two minutes' exposure to undispersed light would make a far greater impression.

The use of green glass is not to be recommended, since it only cuts off red rays, which are comparatively harmless, and materially diminishes the light. In regard to canary medium, it is, I should say, paper impregnated with chromate of lead. It must be recollected, however, that chrome yellows are of different tints. Thus, ordinary chromate of lead can be altered in tint by the addition of nitric acid, and much deepened in colour. It may be, perhaps, advantageous to use such a deepened colour; but as to this I speak with some hesitation, since my experiments in this direction have been very meagre. Let me, in conclusion, say that I have no bias one way or another, and that I should not hesitate to use canary medium of such a quality as has been sent to me in the development of plates. At the same time, I should not care to expose very sensitive plates long to the light coming through it, since I should expect disaster. The point is to use the *safest* light possible—for no light is absolutely safe—and to use the greatest quantity of it within the margin of safety. This was a point laid down by one of the speakers at the January technical meeting, and cannot be too much insisted upon. W. DE W. ABNEY, F.R.S.

LECTURES AT THE ROYAL INSTITUTION.

PHOTOGRAPHIC ACTION.

THE lecturer commenced, on Saturday last, by explaining how it was the vibrations given to the sensitive salt of silver were not visible in the same manner as those in the phosphorescent material. In order to create visibility these two factors were necessary—1. Large amplitude of vibration. 2. An appreciable time. In the case of the sensitive salt the time factor was absent, since the swing of the atoms caused them to separate almost immediately from the molecule. After alluding to the increase of phosphorescence by the application of heat to a phosphorescent plate, and its decrease by the application of a cold body, such as ice, Captain Abney went on to show that precisely the same phenomena were to be found with a sensitive salt of silver. Taking a hot flat iron, which he was apparently just able to touch with comfort, he placed it against the back of a bromide dry plate, and whilst still hot he exposed the latter to light for a brief period and then developed it.

Whilst the greatest part of the plate showed want of exposure the part which had been heated by the flat iron was fully impressed by the light, and a distinct image of the iron was shown. It was pointed out that the application of cold acted in precisely the contrary way, the image of a piece of ice being shown by diminished sensitiveness of those parts which had been in contact with the ice. In both cases the application was made to the back of the plate. It was stated that this action was only transient and did not indicate a permanent change in the molecular state of the sensitive salt, since, if the same process were gone through, and the plates allowed to regain the temperature of the air before exposure to light, no traces of the cold or hot body would be seen on development. This struck us as novel, and we shall probably hear more about the subject outside the Royal Institution, since a reference was made to the fact that it was a phenomenon of practical importance to photographers. An allusion was then made to the probability of a connection between the above described experiments and the shearing stress caused by writing on a sensitive plate.

The next part of the lecture was devoted to the enunciation of the absorption of radiation, and the work performed on the molecules when such absorption took place. The lecturer seemed to think that the heating effect of a body was chiefly confined to causing increased vibration in the molecules where the chemical action was due to the increased vibration of the atoms. The relation of absorption to chemical action was illustrated by spectra taken and developed on the chloride, iodide, and bromide of silver, all of which experiments were successfully carried out. The absorption was illustrated by passing the different films through the spectrum. The connection of absorption and chemical action were further exemplified by comparing the absorption of bichromate of potash, perchloride of iron, and nitrate of uranium in the spectrum with the work performed on them, as shown in the spectra they impressed. The penetration of actinic rays through yellow glass was also shown by direct experiment, allusion being made to an experiment that had failed in a former lecture from that reason.

The different molecular states of bromide were next shown on the screen, an orange, violet, blue, and sap green form being well seen. The lecturer then proceeded to demonstrate why the green bromide should be most sensitive to the ultra-reds, since it absorbed them more completely than did the blue form. A spectrum on paper coated with this kind of emulsion was then taken through ruby glass, the whole of the red end and some of the ultra-red being developed before the audience. A photograph of the carbon points of the electric light were taken through a thickish piece of ebonite, which concluded the experiments.

The lecturer finally called attention to a diagram which showed that the sensitive salts of silver he used had undoubtedly maxima in two localities of the spectrum—one in the blue, and the other an octave below that which lay in the ultra-red.

MISCELLANEOUS SUBJECTS.

So many subjects reappear for consideration again and again before the English photographic societies, it may be useful to point out that one of the utmost practical value is comparatively unworked, namely—

The Influences Affecting True Gradation in Negatives.

Two principal factors will enter into the examination—1. The character and make of the plates. 2. The nature of the subjects and light, these latter being the minor considerations. In England true gradation can be better judged by portraiture than by landscape operations, but in certain localities abroad the difference disappears. When mountains far in the distance, more or less covered with snow, come into the picture the view within a few miles of the camera may be all right; yet the magnificent background may be blotted out entirely if it be more than a few miles distant. The background is then as difficult to catch efficiently in bright sunshine as are natural clouds with the exposure necessary for normal slow landscape plates. Now that commercial plates are improving in uniformity, in being cut to proper size and in absence of elements of spottedness, simple and scientific tests as to their relative power of yielding true gradation, and, if they do not, tests as to *why* they do not, are more wanted than anything else.

Will you allow me to put another than the sulphite-of-soda question to Mr. B. J. Edwards, in whom I have strong confidence, although till your promised exact experiments are produced he has not persuaded me from using the soda salt, perhaps because he printed no comparative way of proving his point. He has published that after fixing a negative in hyposulphite of soda it should not be held up for examination, as the delay may cause stains, but that it should be washed at once. These stains I have never been able to see. Is that because of my use of the sulphite of soda developer?

Recently I corroborated Mr. W. Brooks about the economical advantage of using the pyrogallic-sulphite developer over and over again. Since this corroboration I have been using gelatino-bromide plates extensively for transparencies, because local Swiss photographers do not copy my negatives quickly enough on paper to get off copies expeditiously to London newspapers. Such transparency work shows small differences in the developer much more perceptibly than does negative-developing work. I now find the second use of the developer to give more veil, to lower the intensity, and to prolong the time of appearance of the image. This may be to some extent remedied by the addition of a few drops more pyrogallol and ammonia; but I now never adopt the plan of using the developer a second time when seeking for the very highest results. If a picture I do not much care about has to be developed—such as one containing some additional pictorial details on a larger scale, specially taken merely to guide the engravers—I use the developer a second time, but not to bring out a valuable negative for permanent use. The small economy does not warrant such risk. These objections may possibly be hereafter overcome for first-rate work, but meanwhile the utilisation of the old pyrogallol developer is a subject which requires working out. One use for it is to pour it into old fixing solutions to throw down the silver by long action thereupon.

Wrong speculative ideas may influence large numbers of men for years to their injury, as in the long time during which developing-room operators have been ruining their eyesight in the fetish worship of ruby light. Another species of fetish worship is probably the objection to the addition of the bromide retarder to the pyrogallic acid and soaking the film with the mixture before applying ammonia to the plate. It is known that strong bromide will efface the invisible image; but in the developer the bromide is infinitely weak, and that weakness is further reduced, if not quite counterbalanced, by the developing power of plain pyrogallol. There is a great advantage in pouring these two on the dry film first. The first liquids applied rapidly penetrate the dry, spongy layer, and ammonia is not long in following them, because it is volatile, in which respect it has an advantage over the new potash accelerator. Thus, good fresh developer attacks all depths of the film, which is not the case with the usual method of operating. The advantageous results have so far been to me practically evident in clean, brilliant images and good intensity. When ammonia and bromide are applied together after the film has been soaked there is not alone slowness in the penetration of the sponge by both, but a layer of decomposed, discoloured, and comparatively inert pyrogallol lies between the bottom and top of the sponge, through which the latest chemical additions have to work their way, and probably the ammonia gets through faster than its companion, which separation does not conduce to brilliancy.

Harrison's Theory of the Nature of Gelatine.

Sooner or later I think that gelatine films will have to be supplanted by our old friend, collodion. From a year's series of industrious experiments—not yet available for publication because they are connected with patents—I came to the conclusion that gelatine, like starch, consists chiefly of organic vesicles, and that the same is the case with collodion and gluten; in short, that in photographic films we are dealing with an infinity of what may be called "bladders," more or less filled with organic matter. Here the word "less" more especially applies to collodion, the vesicles of the cellulose having become hardened, dried, and cemented together with resinous coatings, which coatings are softened or dissolved by the acids in the manufacture of pyroxyline, thereby destroying the fibrous texture. If too much action of the acids be imparted the vesicles themselves get destroyed, hence one necessity for carefully regulating times and temperatures when making pyroxyline. To apply these principles to that exceptionally-valuable and closely-reasoned scientific article recently published in these pages by Dr. Vogel, I would suggest his repetition of his experiments by adding various kinds of organic matter to his alcohol before precipitating the silver therein. The specific gravity of the liquid in which the precipitation takes place seems also to have to do with sensitiveness; for in making ordinary gelatino-bromide emulsions the extra concentration of the watery solution in which the precipitation takes place is experimentally proved to increase sensitiveness. It is possible that Dr. Vogel's results were partly due to the specific gravity of the liquid as well as to its chemical nature. Would air or vapour pressure on the surface of the liquid, mechanically applied at the time of precipitation of the silver salt, affect the results? Agar-agar and seaweed gelatines, with which I have experimented for months over other than photographic researches, I believe to be scarcely anything but washed-out vesicles, and think that by adding organic matter to them they may be made to substitute animal gelatine in ordinary plates with very great economy.

As to the best kind of organic addition, that is a point for experiment; but such as Hardwich added to collodion at times and such as were found useful in old dry-plate processes, might be first tried, on the presumption that their use is already backed by a certain amount of practical experience. On this theory, gelatine from different animals consists of different forms of vesicles—differently more or less loaded with organic matter; hence there was much reason in a suggestion a medical man once made to some Scotch photographic society that the photographic properties of the gelatines of various animals—the sheep, rat, horse, pig, and dog, for instance—should be separately tried for dry plates to ascertain their relative properties. What is wanted is to reduce the sponginess of the film, and to increase its quickness of permeability by liquids, without sacrificing any good photographic qualities.

In what has been said herein, of course I know that vesicles are "organic matter," but in a very stable state. By the addition to them of organic matter is meant more unstable animal or vegetable compounds richer (say) in nitrogen. It may also be objected that the vesicles of starch can be seen under the microscope. I know that those of gelatine cannot, but possess strong experimental presumptive evidence that they are present.

The solvents of the colloids I think to act by being solvents of the coatings of the vesicles. Fibrous cellulose is recognised by chemists to be accompanied by hardened resinous matter which it is difficult to separate. My conclusion follows that pyroxyline is, therefore, naturally soluble in ether and alcohol, after the resinous matter has been partly broken down chemically by acids. Gelatine requires warm water to dissolve it. If it be long boiled its setting power is destroyed; in other words, the skins of the vesicles are more or less destroyed, but the chemical composition of the liquid remains the same. Ammoniacal solution of oxide of copper is a most remarkable solvent of the coating of cellulose vesicles; hence its use in limited quantity in making Willesden paper.

Green Light in the Developing-Room.

That those speakers were in error who, at the last meeting of the Photographic Society of Great Britain, made utterances against the value of green screens for light in the developing-room, can be proved experimentally by making a polychromatic negative, as recently described in these pages, with a variety of pairs of green tissue paper. Some of the superimposed greens will be found to print through freely upon gelatine plates; others will be found to stop photographic action as well as Mr. Debenham's green and yellow. Had his combination given a perceptibly yellow or red light, "hot" to the eyes, which it does not, I should now be using a green light exclusively. When doctors supply eye-shades to persons with weak eyes, they would be thought mad if they coloured them ruby or yellow, so black or green are the colours always chosen. It would be bad for the eyes if fields and forests were of a burning red or bright yellow colour, and this is the strongest argument for the use of green. A proper green can be found and used with safety and advantage in the developing-room, if moderate artificial light (I have no experience as to daylight) be used as the original source of illumination, and the earlier parts of the development be conducted not too close to the screen, which should always be at a low elevation in relation to the surface of the plate. Unless the paper screens, tested spectroscopically, be of equal thickness and transparency and amount of staining, comparative experiments are vitiated in scientific value as to the practical utility of different colours. Plates can be developed in safety with any tolerably non-actinic, translucent (not transparent) screen, whatever its colour, if the operator be but careful at what distance and elevation he works from it, so he may as well use a colour good for the eyes. I develope Monckhoven's plates with sulpho-pyrogallol in a good light, without fog, and easily see upon lifting the plate when it is developed to the right intensity, so that after-intensification is never necessary. The question of distance is of more importance than that of colour, and the advantage of a green screen in abolishing light hot to the eyes is beyond doubt to those who try it practically. The error about green light is worth correcting, because it may help to save men from injuring their eyes unnecessarily.

Dry Plates in Switzerland.

The Editors ask for information about English sizes of dry plates in Switzerland. Dr. Monckhoven keeps the English half-plate sizes (perhaps others), at local prices, on sale by his agent in Geneva; with this exception I believe that no plates cut to fit English cameras are on sale in Switzerland. The delays, expenses, and way in which plates ordered from England are spoilt by light admitted by custom-house officers are something awful—in fact, prohibitory. Several English makers sell plates on the continent, but in nearly every case cut only to the sizes used in foreign cameras. W. H. Harrison.

Lucerne, Switzerland, March 18, 1884.

A SUMMER HOLIDAY.

[Abstract of a communication to the Manchester Photographic Society.]

On a Friday night in July, two summers ago, I was deliberating on the wisdom or otherwise of going alone to Switzerland on a tour which I had planned out. I had packed most of my requirements, and, although anxious to go, still I did not relish the idea of solitude, when fortune favoured me in the person of a friend who consented to accompany me on twenty-four hours' notice. It was a great risk going such a long journey with an untried companion for the first time, as I do not think anything tries a friend more than travelling and living together; but, I am proud to say, my friend proved to be the most pleasant companion it was ever the lot of any one to have. Our "out" was the means of forming a deep attachment to each other, which only ended by his lamentable death from an accident.

My apparatus consisted of a Rouch's whole-plate camera, three double backs; Ross's rapid symmetrical lens, eleven-inch focus; Dallmeyer's rapid rectilinear, eight and a-quarter-inch focus; Dallmeyer's $7\frac{1}{4} \times 4\frac{1}{2}$ W. A. P. landscape lens; a Rouch's folding stand, a good supply of Swan's plates, and our esteemed President's collodio-albumen plates. I may here say that during the whole of my travels I have never had the least difficulty with regard to passing the customs with my photographic kit. The moment I get to the examination room I immediately open my kit and portmanteau, courteously explain that it is a photographic apparatus, that I photograph for pleasure, offer to show the contents, and never, in the course of my experience, have I had any further prying, but have passed on at once. The customs officers have a very disagreeable duty to perform, and they can make that duty a very unpleasant one for any shortcomings of courtesy or *hauteur* shown.

We started on the Saturday night with light hearts by the 11 p.m. train for London, and were soon quickly speeding away through the semi-darkness of a summer night. We arrived in the metropolis too early—aye, and had to leave too early—for any chance of a breakfast; so, having two hours to spare, we whiled away the time by taking a walk along the Thames embankment, where many a shocking sight presented itself of the wretchedness of men, women, and children asleep on the seats as we strolled along that beautiful summer morn. Unfortunately I had left my camera at the station, or I should certainly have been tempted to depict this sad state of human existence.

We left about ten o'clock for Dover, and on the steamer we did get something to eat, having fasted nearly sixteen hours. A short, smooth passage, and we were at Calais. There was no time to spare; we started again, through the flat and dreary landscapes of France. A little more patience, and we were at Paris. *Anglais!* the magic word sent us through the customs without trouble. We stayed in Paris until next day, as we thought it better to break the journey there, our next stopping-place being Geneva. Having decided to go by the night mail, we started by the train from the Gare de Lyon about 8 p.m. for Switzerland.

Geneva is the richest and most populous town in Switzerland, and abounds with lovely views, both lake and architecture. The banks of the Rhone are flanked with broad quays and substantial buildings; but the interior has a corresponding effect, the streets with few exceptions being narrow, steep, and crooked. Between the Pont du Mont Blanc and the Pont du Bergues is Rosseau's Island. In the centre stands the bronze statue of the wild, self-torturing sophist himself (by Praden, in 1834). The national monument also is good, and the Duke gorgeous. They are both well worth a plate or two being exposed on them.

Next morning saw us loading a *voiture* (the driver of which looked like a brigand's apprentice, but turned out a very jolly fellow) with our baggage and selves for Chamounix, *viâ* Bonneville Cluses, St. Martin, and Sallanches. The road traverses the new village of Chêne. A few miles further on the scenery becomes more picturesque. Near Bonneville, on the right bank of the Arve, stands a monument to the natives of the department who fell in the campaign of 1870-71; and on the left, 100 feet high, another to the memory of King Charles Felix of Sardinia. Cluses, the next small town, is chiefly inhabited by watchmakers.

The hills here begin to assume the stupendous height and size which so thoroughly defy the traveller to judge distances in this part of the world. The road traverses a district devastated by mud and detritus. At the village of St. Martin we suddenly obtain a magnificent view of Mont Blanc, and though its white and solemn peaks rise majestically into the heavens it is no less than twelve miles distant in a straight line, and seems almost to convey the idea that there is no world beyond. A collodio-albumen plate was exposed here from the bridge, which turned out a very fair negative. Passing onwards through Sallanches we came to the small but popular watering-place of St. Gervais-le-Bains, situated in the wooded ravine of Montjoie. The building is something after the Chinese pagoda style, and I exposed a plate on it with success. As we drove along the glaciers were now visible; but, owing to the vastness of the mountains in which they are framed, it is impossible at first to realise their extent.

At last we arrived at Chamounix, where the hospitable and attentive landlord of the Hotel de Londres received us as brothers and immediately had us ushered up to our bedroom, a metal plate on the door of which bore an inscription to the effect that it had been occupied by Albert Smith, whose famous caricatures of the "Ascent of Mont Blanc" were so famous. Of course this was too good a chance to be missed, so I photographed Mont Blanc from the window. There was a large enclosed yard in front of the hotel, and this was filled with villagers waiting to see the diligences arrive or to hire themselves to excursionists for the morrow. The long porch of the hotel was populous with tourists, who sat under the vast, over-shadowing bulk of Mont Blanc and gossiped or meditated. Mont Blanc is 15,781 feet high. There was a red signal light glowing in the darkness of the mountain side, and it seemed but a trifling way up. That light was on the Grand Mulets, 10,000 feet high above the valley; but in the day-time, even, the foreshortening effect of the mountains create curious deceptions.

Next morning saw us off on mules to Montanvert for the Mer de Glace. From Montanvert we crossed the glacier in safety, but had many misgivings; the crevasses yawned deep and mysterious, and it made one nervous to traverse them. I gave the guide my apparatus to carry, whilst I made good use of the alpenstock, for the huge, round waves were slippery. It was a blazing hot day, and as we climbed along the moraine on the opposite side we could not help thinking that for *pleasure* it was pretty hard work. I exposed several plates on the glacier, also on two pretty waterfalls, and by-and-by came to the Mauvais Pas. It is a winding foot-path round a precipice, with nothing to hold on but some loose iron railing here and there plugged into the rock with wedges of wood, and perhaps 1,000 feet straight down. I got safely across, and wanted my friend to stand in the middle of the pass whilst I exposed a plate, but he declined. However, I made one exposure on it, when another party was coming over.

We now arrived at the Chapeau, where our mules (sent round from Montanvert) awaited us. Of course I had to mount, although I would have much preferred walking; for the mule in mountaineering will persist in walking on the very edge of the precipice. The habit is occasioned, I am told, by the mules carrying packages up the mountain passes, and they take the outer edge so that they can clear the mountain side without scrubbing the sides of their panniers. In a short time we arrived safely at our hotel, after being well shaken up by the mules, for their gait is neither a walk, nor a trot, nor a canter, nor a gallop, but a jogging, shuffling kind of gait which takes all the fun out of one. After that day's excursion I swore off mules, and have never crossed the back of one since.

We left next morning for Martigny by *voiture*. On our way we made a *detour* to the Cascade-de-Bêrard—a picturesque waterfall, in a wild district. Beyond Poyaz the road leads through a valley containing the church of Valorcine, which is protected from avalanches by a barrier of masonry. Pursuing our way we soon afterwards reached the famous rocks of the Tete-Noire. The scenery at this point is indescribably grand and beautiful, and two or three plates may be profitably employed. Proceeding on our journey by a good road we at length arrived at Martigny—a pretty village in the valley of the Rhone.

The next day was spent in visiting and photographing the Gorges-du-Durnant. It is a gorge through which the Durnant is precipitated in a succession of four cascades. It has been made accessible by means of a gallery 870 yards in length, and well repays a visit. The Gorge-du-Trient was another trip. The view is imposing—the rocks, 420 feet high, almost close in overhead, looking like a large cavern. I did not expose any plates here, as it would have required a long exposure and we had not the time to spare; but I often regretted that I came away without doing so, even had I been compelled to stay another day. Cretinism in its most repulsive form exists in this valley, and will ever be remembered by anyone who has seen it. From here we took train for Vernayaz, where we stayed the night, previously making arrangements for an early start next morning by *voiture*.

We left at 5.30 a.m. for Leuk, and soon reached Sierre—a small town situated on a height and commanded by a picturesque old castle. The valleys and mountains really repaid an early start. Just before arriving at Leuk we passed the curious little village of Albinen; it can only be reached by means of eight rude ladders attached to the perpendicular face of the rock, the descent of which is more difficult than the ascent. Shortly afterwards we arrived at Bad Leuk—a village composed principally of wooden houses. It is famous for its springs, twenty-two in number, chiefly beneficial in cases of cutaneous disease. The patients spend two or three hours at a time in the baths, which are something after the style of swimming-baths, and there are floating tables on which coffee and tea and other refreshments are placed.

The huge, perpendicular wall of the Gemmi here presents the appearance of inaccessibility. However, that was our route; so after making preparations and engaging a guide and mule for carrying our baggage, away we went, quite unconscious of the task before us, except we knew it was "a big walk." The road wound in corkscrew curves up the face of the colossal precipice—a narrow way, with always solid rock at one elbow and perpetual nothingness at the other, the upper part actually projecting at places beyond the lower. We met very few travellers, but we always took the inside, and flattened ourselves against the solid rock. Every few hundred yards, when we came to a bad place or sudden corner, there was a little protection by wooden rails.

When we had climbed two or three thousand feet, and looked for a last view of the place we had left, there was presented the charming view of the bright green level, with a pretty town in its midst, and a silvery stream winding amongst the meadows, its background of gigantic precipices clothed with pines, and above all the snowy domes and peaks of the Monte Rosa region. We were soon afterwards amongst the snow, enveloped in cloud and mist, and had to put on our waterproofs. Shortly afterwards we passed the Daubensee—a lake a mile and a-half in length, fed by the glacier waters, with no visible outlet, and generally frozen for seven months in the year. A short distance from here we reached the Schwarenbach, and pulled up for refreshment.

On our downward track, which now began, the path lay through a wild and uninteresting country, enlivened only by the pretty alpine flowers, which seem to grow at any height, until we reached the level of vegetation again. Now beauty after beauty began to be unfolded to our view in the most marvellous manner; and oh! for one half-hour without those fleecy clouds now below, then above, and again all round, dancing and drifting in most fantastic beauty, but never leaving us long enough to permit us to have a "shot." Every turn revealed a new and lovely scene; and, although the journey was long and hard enough to have satisfied a professional pedestrian, I can never forget how enjoyable it was, nor its ever-varying charms. The only view I did get was in one minute afterwards enveloped in cloud and thoroughly hid. However, all things end, and, after eight hours' walking, we reached Kandersteg, where we stayed for the night.

From Kandersteg we left next morning by *voiture* (there is no other method of escape), and soon reached the square tower of the ruined Felsenberg, passing the road which diverges to the Blane See or Blue Sea, picturesquely embosomed in wood, and remarkable for its brilliant effects of colour. The road now was very level, and passing Fellenburg (now a prison), we were soon at Fruitegen—one of the cleanest and prettiest villages I ever saw, situated in a very fertile valley.

Driving on through pretty villages and country brought us to Aeschi, which is situated on a height commanding an extensive view of the Lake of Thun, and here we first saw the Swiss waitress in all the pride of her native costume. Leaving here the rain now began to fall rather heavily, which caused us to have the carriage closed, and drive on quickly to Interlaken. Interlaken attracts numerous visitors, and is noted for its mild, equable climate. The "whey" cure is an inducement for some, whilst many select it as a starting-point for excursions.

We were off in good time next morning for Lanterbrunnen, and had not proceeded far when the Jungfrau, with her dazzling shroud of eternal snow, appeared in all her majesty. Our *voiture* had soon to be abandoned for horses to ascend the path of the Mürren, which leaves the valley and rapidly ascends to the right of the stream. Close by here is the celebrated Staubbauch Fall, which descends in an unbroken fall of 980 feet. Passing along we ascended through a wood to a bridge over the Staubbach; then we crossed two small streams and quitted the wood. We then descended to the valley on the other side on foot (the horses having been left at the top on the Mürren), and are soon in the *voiture*, which has been sent round to meet us. From here we drove merrily, beguiling the time with song and story, until we got back to our hotel.

Next morning our journey was to Grindelwald and the Eismeer. The road gradually ascends the picturesque and well-wooded Lutschenthal, enlivened by numerous farm houses; it then crosses the river four times within a short distance, and ascends more rapidly, passing a small restaurant, at the top of the hill, where there is a good retrospective view. A little further on, beyond a narrow part of the valley, opens the Grindelwaldthal, inclosed by imposing mountains—Eiger, Mettenburg, Sneckhorn, and Wetterhorn. Grindelwald owes much of its reputation to its two glaciers, which descend far into the valley and are easy of access. To obtain a survey of the glacier a visit should be paid to the Eismeer. A narrow but well-kept path ascends the slope to the left, whence a steep flight of steps decends to the glacier. Returning, we turned to the left to view the ice tunnels, which are very wonderful.

Next day we turned towards home, taking train for Darlingen, and embarked on the steamboat for Thun. Arriving there we deposited our baggage at the station, and were soon rambling through this quaint old town, where the guide book informed us 600 people *peacefully* make their living by the war. We left about eight o'clock in the evening, *viâ* Berne and Neuchatel, for Paris, changing at Pontarlier (border customs), and arriving at Paris about ten o'clock next morning. After staying two or three days we arrived safely home, after one of the most pleasant "outs" I ever had.

JOSEPH R. GREATOREX.

ON BICHROMATED GELATINE FILMS AND THE STANNOTYPE PROCESS.*

BEFORE going on to consider the process by which the mould is obtained, a word or two regarding the special form of tissue that is required may be necessary. For those who may work the process prepared tissue can be had from Mr. Woodbury. Here is a specimen of it. As you will see, it has very little colouring matter in it. The colouring matter here, as far as the mould is concerned, is superfluous; but it was found necessary to have a little, so as to judge of the developing of the mould. The tissue can be prepared by the amateur should he be so minded, and the formula for preparing the same is to be found in an article on stannotype which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY of February 18th of the current year:—

Gelatine	4 ounces.
Glycerine	½ ounce.
Sugar	180 grains.
Colouring	as required.
Water	16 ounces.

The sugar and glycerine are dissolved in the water, and the gelatine allowed to swell therein. The gelatine must be of an easily soluble kind. Nelson's is recommended. After all is dissolved by heat the colouring matter (liquid indian ink does very well) is added. The mixture, after filtering, is ready to be poured on to glass plates, accurately levelled and previously coated over with ox-gall. The plates can be made into shallow trays by surrounding them with pieces of wood, which can be removed so soon as the gelatine has set. The plates are now dried in an apartment or drying-cupboard at a temperature of about 70°. The gelatine takes about two days to dry. Sheets of paper, cut to the required size, are then wetted and applied to the film by means of the squeegee, and after two hours' further drying the paper will be found adhesive. The tissue can be kept on these glass plates till actually required. Here is a specimen of home-made tissue.

We come now to the sensitising of the tissue. A six-per-cent. solution of bichromate is required, and the time of immersion five to six minutes. After sensitising and allowing to drain, the tissue has to be dried; and, as drying by heat is objectionable, as the tissue might be thereby rendered insoluble, a special mode of drying has to be adopted. For this a drying-box with chloride of calcium is necessary, and such a box you have here. By sensitising over night and leaving the box in a somewhat warm room the tissue should be ready for use in the morning. It is necessary that the chloride of calcium be fresh, to give satisfactory results. The exposure of the sensitised tissue behind the prepared transparency must be regulated by the photometer. It should be stated, however, that behind the tissue in the printing-frame a piece of india-rubber cloth or oilskin paper, such as is used in copying letters, should be placed. As to the necessary exposure, experience will be found to be the *sine quâ non*. The exposure over, the tissue is developed on patent plate glass, collodionised as in the case of preparing the transparency. After the tissue is squeegeed on to the plate the glass should be covered with blotting-paper, a sheet of glass laid over it, and the whole subjected to some heavy weight. A quarter of an hour or so thereafter development may be proceeded with. This is a somewhat prolonged process, occupying from about three to five hours. It is evidently a matter of considerable judgment to determine when a mould has been sufficiently washed. The water to be used in the development must be at a temperature of about 110° Fahr.

When the mould is sufficiently developed it is rinsed with hot water, and then with cold. After draining it is removed to a dish containing fresh methylated spirit and allowed to remain for several hours. The gelatine is thereby deprived of its water, and on the mould being removed it very quickly dries. Black spots on the mould, due to defects in the transparency, can at this stage be removed; and for this purpose a strip of glass with a clean fracture across will be found most serviceable. The mould is now ready to receive its coating of tinfoil, only before doing so a solution of india-rubber in benzole is poured over the mould, as in coating a glass plate with collodion. A thicker solution of india-rubber is passed round the edges of the glass by means of a brush. Having cut a piece of tinfoil to the size of the glass, free from holes, the tinfoil and the glass are put together through the rollers of a domestic wringing-machine—one with india-rubber rollers. The rollers have to be separated sufficiently far apart in the first instance to allow the glass and foil to enter freely, and when the centre of the glass is between the two rollers pressure is applied and the glass worked gradually backwards and forwards, extending the motion till both edges of the glass be reached. It is necessary to start in the centre of the glass to avoid any bubbles getting between the mould and the tinfoil. When finished the mould presents an appearance similar to the specimen which I now put forward.

The press claims our next attention, and here it will be seen that Woodbury's mechanical ingenuity comes into play. As it is on the table there will be no need to describe it. The mode of using it is as follows:—Having cut a piece of stout blotting-board to the size of the glass, and, having steeped it in water and allowed it to drain, it is placed thereon, and all the screws having been loosened the top part of the press is allowed to lie freely of its own weight on the mould. The press is then closed by pushing the handle forwards, and the screw under the arch of the press screwed up as tightly as possible, thereafter the top screw, and lastly the screw which fixes the ball-and-socket joint. On releasing the handle the top part of the press lifts as a whole, and will always fall back again to the same position.

The mould is now greased with a mixture of salad oil and paraffine oil by means of a piece of flannel, and we are ready to draw proofs. A word as to the ink employed. It is simply gelatine dissolved in water—one ounce of gelatine to six to seven parts of water, and with colouring matter added to suit the particular requirements of each mould. The photographic tint, which we are all so much accustomed to, is arrived at by means of a mixture of carmine and indian-ink, or alizarine and indian-ink. A deep mould requires less colouring matter than a shallow one. The temperature at which the ink should be kept is somewhere about 120° to 130° Fahr.

At this stage it may be as well to close this paper and proceed to throw off a print or two from the mould which at present is lying on the bed of the press. The mould is not quite such a perfect one as I could have wished; but as I was afraid, on account of the defective light we have lately been having, that I was going to be "short shipped" altogether, I was only too glad to get one at all to show at this meeting. Since taking to stannotype I have only prepared two moulds altogether, so that I bring the process before

* Concluded from page 205.

your notice under somewhat imperfect conditions. Had the light been better than what we have been lately experiencing, I feel justified in saying that more perfect results would have been obtainable.

Mr. Woodbury, knowing that I was to communicate something regarding his process to our Society, has very kindly sent down some of his printing moulds. He has also sent down some magnificent examples of stannotype prints. I think for this attention he should receive our most cordial thanks. I think also you will admit that the work produced is magnificent; and that there is a great future for stannotype there cannot be a doubt. Mr. Woodbury deserves all success in the process which he has devised, and I am sure the members of the Glasgow and West of Scotland Amateur Photographic Association will join me in wishing him that his success may be of a kind that will benefit himself in no stinted degree. W. LANG, Jun.

PHOTOGRAPHIC NOTES OF A VOYAGE FROM LIVERPOOL TO TRIESTE IN A CUNARD STEAMER, JANUARY, 1884.

[Abstract of a communication to the Liverpool Amateur Photographic Association.]

MY photographic "kit" was a "scratch" one. The idea of the journey being sudden, there was but little time to scrape an outfit together. We left Liverpool in the S.S. "Aleppo," on January 11th.

As we neared Gibraltar I took a photograph of the old Moorish town of Tarifa, but, owing to the distance, it is worth nothing. A general view of the continent of Africa shares the same fate, and the views of the rock itself as we neared it towards sunset are not good.

We left Gibraltar at sunset, and as we rounded Europa Point the views were grand. Two plates were tried, but with the result of under-exposure. The fine red mountains of Cape de Gata formed the next subject, at 7.45 a.m. This picture is unavoidably a mere strip across the plate, owing to the distance and to being taken from the steamer. It seems almost impossible to get an artistic view of land while passing in a steamer. As a rule there is no object to form a foreground, and the straight line of the horizon is not picturesque. The next subject—a ship off Cape Palos—would have formed a lovely picture if the glories of the Mediterranean sunset behind could be portrayed. Every tint, from crimson to pale green, overspread the sky, and as a rule we generally had these grand effects.

On January 21st, at 8 a.m., we put in to Genoa for two days. Genoa is a splendid city of palaces, and possesses many ancient and picturesque buildings, as well as numerous streets so narrow that you could shake hands from the top stories with your opposite neighbours. The houses in these streets are taller even than those of Edinburgh, and are full of fascination for the photographer. You come upon large public washing troughs in open courts, with women all round at work; and clothes hang across the narrow alleys. I tried a plate at the head of a court looking down on a public washing-trough, but, unfortunately, it was under-exposed. A great but polite crowd stood round the camera watching the proceedings, even unto the packing up and shouldering of the same. Then, no doubt thinking that the "show" would open down the next "slum," these kindly Italians prepared to follow, upon which I took off my hat and handed it round. Result: *nil*; but the crowd dispersed, abashed, to their own homes. The people in almost all the towns were most polite, grasping the situation at once and actually helping to keep others from passing when they saw that the camera meant business. No mention of Genoa would be complete without the cemetery. It is a few miles from the city, and forms a fine collection of good Italian sculpture. In many cases life-sized statues of the sorrowing relatives ornament the monuments, and in others figures of angels, &c. Several hours might be spent there with advantage.

The views on entering Naples are numerous and fine. Here I must remark that if our Captain could have thought more of photography and less of his ship we might have steered closer in shore and obtained better results. Passing Ischia (six miles distant), we could well discern with a field glass the ruined houses and other results of the late earthquake, but the distance was too great to allow of details in the photograph. The town of Procida on its rugged height forms another fine subject; the distance here also was great. The smoke of our steamer rather helps the effect in the sky. Vesuvius, with the collection of small, dirty towns along its base came next—the steamer coming into the Bay of Naples at about twelve knots at the time. A view of Naples was also taken, but, owing to the lateness of the hour, the result was not pretty. Here we had only one day, and the time was too valuable even for photography. A slow train conveyed us to Pompeii in the morning, and in the afternoon we visited what must be one of the most interesting museums in the world—that of Naples.

Leaving Naples on the evening of the 24th we steamed into the beautiful harbour of Palermo at mid-day on the 26th. Here, as we rounded the grand mass of Monte Pellegrino, the subjects were very good and the light most brilliant; but, unfortunately, the most sensitive plates being in the slides at the time, the pictures were much over-done. Having only one afternoon on shore I could not attempt photography to the detriment of sight-seeing.

We left that night, and, rising early next morning, could see Stromboli behind us as we entered the lovely Straits of Messina.

Leaving on Monday night in a black thunderstorm, the contrast between it and the peaceful Sunday morning was great—the one a harmony in silver and grey, and the other a regular "Whistler" in indigo. A wild night succeeded, and had we not been under the shelter of the land there would have been dire woe on board. As it was, the wind howled among the rigging as we went along at half speed, in order to avoid reaching Catania before daylight. The steward having orders to call me early if anything photographic was about, at daylight he reported Etna on the starboard bow. The sight on reaching deck was very fine. The Queen of Volcanoes covered with fresh snow, and in a wreath of delicate, early morning mists was a lovely sight. The squall was still on, and the mountain rather distant for photography. We lay off the port, not daring to enter in the storm; but during breakfast the wind changed and we were soon in Catania. While entering, two views were taken, and we were soon ashore looking for subjects. The cathedral and street views were good, but the most interesting picture, and one that fascinated me greatly, was a congregation of more than one hundred women washing clothes. They were in four rows; two rivers of water ran between them, and through a garden to the sea. The brilliant sun and the many picturesque colours of the women and clothes formed a sight that would gladden the eyes of any artist. It was but the work of a moment to set up the camera and photograph the ladies before they knew what was going on. In the photograph many are in shadow, but if enlarged every figure would stand out.

January 30th being a hot summer's day, a few of us took a trap along the shore road for four miles to Aci Castello. Everything along the coast was volcanic, and seemed to have come down from Etna, whose summit is twenty-six miles off. We were told that Catania had been partially destroyed by Etna six times, but the hopeful natives still go on building.

Syracuse was our next port, and unfortunately we had only one day in this interesting city. There are many fine ancient remains. The Greek theatre is one of the finest sights. Situated high up it forms a good foreground to the distant city on an island. Many pretty studies might be made of the manners and customs of the villagers. The women stand outside their doors with a primitive distaff in one hand, and by a dexterous spin of a bobbin hanging therefrom they spin the flax as it passes glibly through the fingers. The small tradesmen sit outside in hot sun at their work without hats, apparently courting sunstroke and the blindness, for as soon as the sun is off their side of the street they convey their bench to the opposite gutter, and again bask in the afternoon sun. The old ladies enjoy a peculiar sport, and one is often to be seen at the house door, with the head of the pet of the family on her knee, diligently searching for something that is not wanted. This seemed to be the afternoon recreation of the grandmother. As all these little *tableaux* take place in the sunshine, the instantaneous shutter might be usefully employed.

Leaving the warm, sunny land of Sicily, with its groves of ripe oranges and lemons, we steered straight for Trieste with a large cargo of fruit on board. Nothing of interest came within range until we reached that fine port. The shipping of Trieste and the beautiful cattle which draw the carts make good photographic subjects.

Here we left our steamer and started for Venice in a small vessel, the ordinary length of voyage being seven hours. A heavy fog coming on, we did not reach Venice for seventeen hours. The steamer not being properly provisioned, our breakfast consisted of a cup of tea and dry bread, and on clamouring for dinner each passenger had the following sumptuous repast set before him:—Two sardines, a cut of dry salt tongue, a glass of wine, and some bread—so hard that it was all we could do to break it with a knife handle. We arrived at Venice at 6 p.m. in time for the *table d'hote*. The fog lasted four days, and we saw but little till Sunday, when we had perfect weather. Twelve plates were exposed on that day, the last two from the top of the Campinile of St. Mark's, at sunset.

The "Aleppo" had meanwhile arrived, and I took all my photographic things and one hundred plates (to be developed on my return) on board, on Monday morning, to be taken to Liverpool. My friend and I said goodbye to the captain, officers, and passengers, with whom we had passed a delightful three weeks. From a gondola we watched the good ship sail away for Liverpool, and for the moment felt alone in the world—without friends, and without camera. We quickly recovered, however, and much enjoyed four weeks more of travel, spending a glorious week of sunshine in Rome, and coming home by Florence, Milan, Brussels, and Calais. As far as I could judge, Italian photographers, for the most part, still revel in the dark ages of wet plateism, and the ancient chemical collodion is still largely in vogue. G. E. THOMPSON.

UNIVERSAL ATTRACTION: ITS RELATION TO THE CHEMICAL ELEMENTS. BY W. H. SHARP.

Edinburgh: E. and S. LIVINGSTONE.

THIS is a work of fifty-three pages devoted to a consideration of the atomic theory, in which the author endeavours to render clear some of the less easily explicable points in already-accepted theories. Starting with the thesis that so far as we are taught up to the present time "the atoms used by Nature are of about sixty-five different kinds, and that if they are of equal weights they are of the oddest sizes, and if, as is generally assumed, of equal sizes, Nature has made them of the oddest possible weights," the author proceeds to express his opinion that it is a "libel upon Nature" to imagine that she chose these "odd" figures without a sufficient reason. He then goes on to develope his own views, which involve, in the first instance, the impeachment of the Newtonian law, and attempts to find satisfactory definitions of the terms "mass" and "weight," but confessedly without much success. We cannot, however, here discuss the matter in detail; suffice it to say that Mr. Sharp holds that gravity, like sound, light, heat, electricity, and magnetism, is propagated by wave-motion, and that gravitic force is at least as important a factor in physical phenomena as any of those mentioned. One short quotation will show the style of the author's argument. He says:—"Take a body which in the earth's field of force has a certain weight. By the scientific use of your imagination weigh it in the various portions of the terrestrial spectrum produced by admitting gravitic force through a prism into a room from which all other force is supposed to be excluded. Note the changes of weight, the special influence of certain waves, and that the body itself remains unchanged."

We must, however, leave those of our readers who may be sufficiently interested to study these purely hypothetical arguments for themselves.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on Thursday, the 27th ultimo, the chair was occupied by Mr. W. M. Ashman.

Mr. A. Cowan showed a machine for wiping the backs of plates to clear off, before putting them to set, any emulsion which might have flowed underneath whilst coating. It consisted essentially of two arms, nearly parallel, pivoted horizontally, at just such a distance apart as to allow the hand with the pneumatic holder to pass between them. The plate being laid upon these arms and held down upon them, a treadle was pressed which caused the arms to separate, wiping the under side of the plate in so doing. Long bands of flannel wound on rollers passed over the top edges of the wiping arms, and by a ratchet-wheel arrangement were wound off about three-eighths of an inch at each time of using, so as to present a fresh dry surface for each plate.

Mr. A. L. Henderson proceeded to demonstrate a new method of preparing emulsion. He said that the formula which he would then give was not perhaps the best that could be given; but it would illustrate the principle, and he would show the results of further experiences at a future meeting. Instead of converting the silver into bromide in the presence of a colloid body it was first formed into an acetate. He took a solution of 170 grains of nitrate of silver dissolved in six ounces of water and poured into another solution which had been prepared by dissolving 147 grains of carbonate of ammonia in water and neutralising with acetic acid, the quantity being made up to six ounces. Into the vessel containing the acetate of silver was now poured a solution of 120 grains of bromide of potassium and two grains of iodide of potassium. The precipitate having subsided and the supernatant fluid poured off, gelatine solution was added at a temperature of about 120°, and in a short time the bromide was found to have been formed into a fine orange emulsion. In order to obtain rapidity ammonia would be added and the solution kept warm for some time. In making an emulsion he preferred to use a small quantity of gelatine with the acetate of silver before adding the bromide, but he wished to prove that it could be dispensed with. He had now done what he had stated the week before he was prepared to do, namely, formed an emulsion of bromide of silver in the absence of a colloid body.

Mr. A. Mackie inquired whether, in forming the acetate of ammonia solution, it was important that either the acid or the alkaline should be in excess.

Mr. Henderson said that this was one of the points which required to be worked out, but he thought it was best neutral.

Mr. W. E. Debenham asked whether the rapid plate shown by Mr. Cowan at the last meeting, as being of Mr. Henderson's preparation, was made according to the formula given, and whether gelatine had been used in the first instance.

Mr. Henderson replied that some gelatine had been used before adding the bromide in that case. He would bring the formula used for that plate to the next meeting.

Mr. Debenham said that the formation of the bromide from the acetate instead of from the nitrate had evidently an important influence; for the coarse-looking precipitate became thoroughly emulsified, which it would not have done had it been formed from nitrate of silver in the absence of a colloid body under similar conditions. Some years ago Captain Abney had introduced his method of emulsifying a washed precipitate of bromide of silver. He (Mr. Debenham) had tried the plan, and found that for a slow emulsion it was successful, but that if he endeavoured to get rapidity by long digestion or other means weakness and fog supervened. On one point he must differ from Mr. Henderson: he could not consider that the bromide of silver was emulsified until the gelatine was added, as up to that time it was a precipitate, although a little of it might remain for some time suspended in the supernatant liquid.

Mr. A. Haddon agreed that there was not emulsification, but precipitation, in the first stage of the preparation.

Mr. Mackie said he had tried Captain Abney's method as it was first published, without any gelatine before precipitation, and could get an image. He requested that Mr. Debenham would define what emulsification was.

Mr. Debenham replied that there had been considerable differences of opinion on the point, and he could only give his view without pretending to consider the question as settled. He considered that emulsion consisted of a mixture of two substances—one of which must be a liquid—not chemically combined, but so intimately mixed that they would remain for a considerable time without separation.

Mr. Mackie was of opinion that emulsification was a mixture of two substances by the aid of a third. He inquired whether Mr. Henderson preferred to pour off the water containing the soluble salts, as he had done that evening, or to add the gelatine and wash afterwards in the usual way.

Mr. Henderson preferred the latter course. He could never get quite the quality unless the gelatine was subjected to the nitrates.

Mr. J. B. B. Wellington inquired how much emulsion the silver used (170 grains) would make.

Mr. Henderson replied that it would make from ten to twenty ounces. He preferred to make it up into the smaller quantity. In answer to a question as to the rapidity of an emulsion prepared as shown, he said that it would be fairly rapid, but would be more so if ammonia were added and it was then digested, the change took place very quickly.

Mr. Cowan remarked that if the rapidity depended upon the time of digestion with ammonia, the last plates of a batch that was being coated would be more rapid than the first.

A question was asked as to the heat at which the emulsion might be digested, after the addition of ammonia?

Mr. Henderson could not say.

Mr. Debenham said that in his experience the effect of a high temperature upon the emulsion that had been washed and had had ammonia added, was to render it foggy and useless. An hour or so at 150° was sufficient to spoil it completely.

A communication to the Society, sent by Mr. R. Offord, was read, *On Taking Stereoscopic Pictures on Quarter Plates*. The plan advocated by Mr. Offord was to pose the sitter on a revolving stand, to which a head-rest was attached. Between the two exposures a partial revolution of the stand was made to give the necessary different view. A contrivance was fitted up with cardboard in the camera back for shifting the quarter plate, so that one half of it might be exposed at a time if one lens only were to be used. Mr. Debenham said that a twin lens camera was best, as the silk was less likely to move; but that if made with one lens the principle of the old shifting camera known as "Latimer Clarke's" was better than that of moving the sitter. The use of such small pictures as the half of a quarter plate he thought a great mistake. The photographs should be as wide as the stereoscope allowed—that is, about two and a-half inches. It was, indeed, considered by some a disadvantage that wider prints than that could not be used. Stereoscopic pictures were certainly beautiful objects, and he thought it a pity that the fashion for them had so much gone out. Could not photographers do something to revive it?

Mr. Cowan said that it was certainly *the* best form for portraiture.

Mr. Debenham showed a travelling lantern fitted with yellow paper and green oiled silk, as described in our report last week of the technical meeting of the Photographic Society of Great Britain.

The Chairman announced that the next monthly lecturette would be given on the 10th instant, by Mr. W. E. Debenham, *On Lenses*.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

The eleventh general meeting of the session of this Society was held in the Religious Institution Rooms on the 20th ult.,—Mr. Robert Dodd, Vice-President, in the chair.

After the minutes of the previous meeting had been read and confirmed, and the question-box disposed of,

Mr. Wm. Lang, Jun., read an interesting paper *On Bichromated Gelatine Films and the Stannotype Process*. [See page 201 in our last issue.] He also demonstrated the working of the process, which seemed both simple and satisfactory. A number of specimens, lent by Mr. W. B. Woodbury for the occasion, showing first-class work at all the different stages, were very much appreciated by the meeting.

Mr. Robertson then gave a general description of the original Woodburytype process, and exhibited a number of lead printing blocks, and impressions from them, which had been sent to the Association by Mr. Woodbury at the time the process was patented.

Votes of thanks were then awarded to Mr. Woodbury and Mr. Lang, and the hope was expressed that more practical demonstrations would be given at future meetings.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held in the Free Library, on Thursday, the 27th ultimo,—Dr. Kenyon, President, in the chair.

The minutes of the February meeting having been read and passed, Messrs. Archer, Durnford, McMurtrie, New, and Williams, were elected members of the Association.

The Hon. Librarian (Mr. J. H. Day) announced that he had received the following donations to the library:—A volume of the *Photo. News* from the Rev. H. J. Palmer, the records of the Photo. Society of Philadelphia, and eighteen lantern slides from the Hon. Secretary. Mr. Day expressed a hope that many members of the Association would now follow the good example which had been set them, and present numerous transparencies for the lantern to the small collection at present connected with the library.

The Hon. Secretary read a letter from an American amateur, enclosing some views of American scenery, and asking for English photographs in exchange.

Mr. B. Boothroyd gave some details with regard to Rufford Hall and its surroundings, and kindly consented to undertake the management of the excursion thither on the 26th instant.

Mr. G. E. Thompson then read his paper entitled *Photographic Notes of a Voyage from Liverpool to Trieste in a Cunard Steamer, January*, 1884 [see page 220], and exhibited a large number of interesting and beautiful pictures taken by him on his recent tour. He said, moreover, that he had used Mr. Kirkby's shutter, and also one recommended to him by Mr. Forrest. Both had given good results; but he had met with some difficulty in obtaining sharp pictures, owing to the vibration of the stand. He (Mr. Thompson) exhibited the whole of the apparatus used by him on his journeys.

The Chairman proposed a cordial vote of thanks to Mr. Thompson for his most interesting and useful paper, and, referring to the fact that some of the seascapes were over-exposed, said that lenses should be stopped down when rapid plates were exposed at sea.

Mr. Day spoke approvingly of the views of shipping, &c., taken years ago by the Rev. H. J. Palmer with a simple cardboard shutter; but he thought, on the whole, that the shutter devised by Mr. E. Roberts was the best for this class of subject.

Mr. R. Crowe remarked that over-exposed seascapes could always be saved by care and management in the development.

Mr. J. H. T. Ellerbeck spoke very highly of Edwards's shutter, and thought the results exhibited by Mr. Edwards were among the finest instantaneous pictures produced.

The Hon. Secretary reminded members of the neglected condition of the Society's album, no prints having been contributed to it for some time.

The Rev. H. J. Palmer gave an account of some further lantern experiments, which he had been making with the pamphengos and the pentaphane, since the last meeting. Mr. Watts had had one of Archer's reflectors substituted for the ordinary pamphengos reflector, but Mr. Palmer had failed to detect the slightest increase of brilliancy.

Mr. Blanchard passed round an album of views, among which were some extremely interesting pictures taken at Lagos, and other places on the coast of Africa.

Mr. A. Beer exhibited some very fine enlargements from 10 by 8 negatives belonging to him, made by Mr. J. Harmer, of Littlehampton, Sussex.

Mr. Thompson showed his camera, lenses, and shutters, a large number of views in the Mediterranean, Sicily, Naples, Trieste, and Venice, and also a portable Buckle stand with some improvements by Mr. Crowe.

The meeting was then adjourned to the last Thursday in April.

PHOTOGRAPHIC SOCIETY OF IRELAND.

The annual optical lantern exhibition of this Society was held on Friday last, the 28th ult., in the Royal College of Science, Stephen's Green, E. As on former occasions, the transparencies were taken from negatives the work of the members during the past year, nearly all being produced on collodion films, the majority of the pictures evidencing a marked improvement on former work.

The following pictures called forth well-merited applause:—*Interior of Ruins of Glastonbury Abbey*, by Mr. F. C. Allen; *Interior of Bruges Cathedral* and *Interior of St. Paul's, Antwerp*, by Mr. H. Bewley; *A Snow Scene*, by Mr. Conan. This was an exceedingly pretty picture, the snow being rendered very effectively. Mr. Pim's *Studies of Trees* were very interesting and beautiful, he having made a speciality of this "branch" of photography during the past summer. The yawl *White Rose*, by Mr. E. P. Johnson, was, as one of the members remarked, "a real gem." It was taken from a punt in Killiney Bay, Dublin, Mr. Johnson holding the camera in his hand while he made the exposure. A selection of views, taken by Mr. J. L. Robinson, in Normandy, Lisieux and Bayeux, were also much admired.

The evening was most enjoyable, and to judge from the attendance—nearly 400 ladies and gentlemen being present—the interest taken in the exhibition was most encouraging.

The following members also sent in contributions:—Messrs. Curtis, Baker, Webb, Robertson, Bewley, Mitchell, Scott, Roper, Watson, and others. The next ordinary meeting will be held on Friday, the 9th May.

PHOTOGRAPHIC SOCIETY OF VIENNA.

This Society met on the 15th February, when the chair was occupied by Dr. E. Hornig, President. The minutes of the previous meeting having been approved, and a new member admitted,

The Hon. Secretary (Herr Luckhardt) read the report of the committee appointed to award the Voigtländer prizes, which they did thus:—A silver medal to Lieut. David, for his studies in emulsion photography, for the results of his labours as a photographic amateur, and for the construction of various useful pieces of photographic apparatus. A silver medal to Dr. Bruno Meyer, of Karlsruhe, for his transparencies (numbering several thousands) intended for educational purposes, and for his catalogue, compiled with great industry. A bronze medal to Herr Bopp, of Innsbruck, for a collection of stereoscopic photographs on glass from injected anatomical preparations, and especially in consideration of the difficulties which had to be overcome in taking such subjects. A bronze medal to Herr Schapiro, of St. Petersburg, for a series of interesting physiognomical studies, with accompanying explanatory text, in which the actor Burlack represented various scenes from the life of a madman. A bronze medal to Herr A. Tockstein, of Vienna, for his efforts to construct apparatus practically adapted to photographic purposes, and particularly to the emulsion process. The committee, at the same time, thanked all those gentlemen who had assisted to make the meetings of the Society interesting either by communications made directly to the meetings or to the Society's organ—particularly Herren Gelpke, Mariot, Scolik, Scamoni, Major Volkmer, Dr. Lorent, and Captain Pizzighelli.

Baron Stillfried then gave an interesting sketch of the condition of photography in Eastern Asia, particularly in China, Japan, and Siam. In the last-named country it had for some time back met with little encouragement. In China and Japan there were some native professional photographers; but their productions were rather black and white affairs, and did not display much taste. The apparatus used was of a very primitive make, the chemical knowledge being of the slenderest description. For landscape photographs there is no demand at all, the only sale for them being amongst amateurs and collectors in Europe or the United States.

The Chairman, in thanking Baron Stillfried for his communication, announced that there would be an exhibition of that gentleman's Asiatic views, &c., on the 12th February, at the Imperial Royal Museum of Art and Industry.

The attention of the meeting was next directed to the objects placed upon the table for inspection, and Major Volkmer was asked to give a short account of the *heliogravures* shown by the Military Geographical Institute.

Major Volkmer remarked that, in the case of the picture of General Von Wanka—said to be by the Klic process—that expression was not to be taken too literally, but merely to be held as indicating that it was by a heliographic etching process.

The members of the Society had a good opportunity of comparing the process as worked at the Institute by Herr Sommer with Herr Klic's process. The following applies generally to both. An ordinary negative—such as can be used for printing from upon albumenised paper—is taken, and a positive upon glass printed from it by means of carbon tissue, consisting of very soluble gelatine with a rich addition of sugar (in order that the picture may not be in high relief) and fine lampblack. This positive upon glass may easily be retouched either with lead pencil or neutral-coloured ink. A negative picture, exhibiting a delicate relief, is then produced from this positive matrix upon a copper plate (rolled copper) having a granularity produced by asphalte powder, and which is also prepared with very soluble gelatine, sugar, and lampblack, but which also contains a suitable addition of carbonate of magnesia and albumen. This picture, in delicate relief, is then etched into the copper plate by means of a rather concentrated solution of chloride of iron. The iron chloride first hardens the gelatinous film; but at last the etching solution gradually penetrates through that film to the copper, the metal being, more or less, attacked according to the degree of relief at which the gelatine film stands out at the different places. After this first etching the gelatine picture and asphalte granules are both removed from the plate, which then shows but a flat and monotonous picture; but second, third, or even more subsequent etchings bring it up to the desired power and depth. Preparatory to this supplementary etching the surface of the plate is protected by a smooth leather roller, saturated with some fatty, acid-resisting ink, being passed across it and then warmed in order to close the particles of colour. The most delicate tones take on the ink, and those beyond, which require to be further etched, remain open and may be acted upon for a minute or two by the etching medium. On repeating this procedure the quantity of colour taken up by the roller and the amount of pressure with which it is applied to the surface of the plate are increased, and the time of etching may be doubled. A third or fourth coating of ink is applied, so that only the deepest shadows shall remain open, and these may be etched three or four minutes. The negative from which the particular picture shown was done was taken by Herr Luckhardt.

Dr. Eder showed a number of instantaneous views by M. Lugardon, and spoke of Mr. H. P. Robinson's method of introducing figures so as to give life to even the most monotonous landscapes. He (Dr. Eder) then communicated his latest researches in the region of gelatine emulsion.

Herr Scolik gave an account of his experiments with a variety of developers (particularly Nelson's).

The Chairman placed on the table the first number of the Portuguese publication, *La Arte Photographica*, to which La Senorita Relvas contributes a landscape illustration, and the first number of *Der Praktische Photograph*, which hails from Breslau.

The meeting was shortly afterwards adjourned.

Correspondence.

"FREE LANCE" AND THE MANCHESTER PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—I very much regret that owing to the unavoidable, and almost unprecedented, absence of the Secretary at the February meeting of the Manchester Photographic Society the discussion on the subject of swing-backs was not as fully reported as it was desirable it should have been; and I still more regret that Mr. Rishton's able lecture, which was mainly extempore, and illustrated by a very clever model, was not reproduced in the report of the proceedings. Had this been done considerable light would probably have been thrown on what "Free Lance" is pleased to call a series of "mixed statements."

As this vivacious writer has, apparently, "caught me tripping" I wish to point out that what I did say, had I been fully reported, was that the axis of the lens being placed in an oblique direction to the surface of the plate, and also pointing obliquely to the perpendicular front of a building, but at an opposite angle—a condition of things which obtains when the swing-back and tilted camera are used—*must produce distortion*. I further endeavoured to point out that this opposite angle formed by the axis of the lens with the front of the building, being photographed, was an important factor in the problem, and one not sufficiently taken into account.

I quite admit that the swing-back will preserve the parallelism of the perpendicular lines when the camera is tilted; but it does so at a serious expense of uniform definition, and leads to horizontal distortion, very noticeable near the top and bottom edges of the plate.

As the discussion on the subject will be reopened at the April meeting of the Manchester Photographic Society by a communication from one of the members, who will show the results of some test experiments, I will not at present proceed further to elaborate the argument.—I am, yours, &c.,

Manchester, March 31, 1884. J. S. Pollitt.

SODIC SULPHITE—"POST FINAL."

To the Editors.

Gentlemen,—Before the final close of this discussion, I should like to thank Mr. Herbert B. Berkeley for his kind and courteous offer; and in return—as it appears that gratuitous advertising is the order of the day—I beg to say that I shall be happy to supply him or others of your readers with extremely sensitive dry plates which, with ordinary skill in developing and without sulphite of soda in any form, will give the "wet-plate quality" so much admired by Mr. Berkeley, and also by—Yours, &c.,

March 31, 1884. B. J. Edwards.

SULPHUROUS ACID IN THE DEVELOPER.—SCREENS.

To the Editors.

Gentlemen,—As to the objection of "Free Lance:" if he read the article again he will see that by the method of development the film was well soaked with free sulphurous acid before the ammonia reached it.

Will Mr. W. E. Debenham kindly post me a small fragment of the green oil silk? Mr. Fry has sent me a fragment of "true" canary medium; but as its safety is due to its opacity, and as it blocks out twice as much useful light as my present screen, I prefer to work in the bright and cool light.—I am, yours, &c., W. H. Harrison.

Hotel du Lac, Lucerne, March 31, 1884.

MEASUREMENT OF SPEED OF SHUTTERS.

To the Editors.

Gentlemen,—I see from your report of the last meeting of the Photographic Society of Great Britain that Mr. C. Ray Woods claims for Captain Abney the tuning-fork method for determining the duration of exposure in connection with instantaneous shutters.

When I read a paper on this subject, some time back, I was not aware of the fact that Captain Abney had published anything in this direction. Had I known it I should most certainly have mentioned the Captain's name in my communication.

Will Mr. Woods kindly give date, &c., when Captain Abney *first* published his method? Awaiting reply,—I am, yours, &c.,

Royal Naval College, Greenwich, S.E., March 31, 1884. A. Haddon.

A QUESTION OF PRIORITY.

To the Editors.

Gentlemen,—In a paper by Mr. W. Lang, Jun., printed in your last issue, I see that he attributes to Captain Abney the discovery that an image impressed upon bichromated gelatine is capable of impressing in turn another bichromated film.

Will Mr. Lang be good enough to state where this was first published by Captain Abney, as I have an impression that it is a discovery of very long standing?—I am, yours, &c., A. Collier.

23, *West Hill-street, Brighton, April* 1, 1884.

Notes and Queries.

Geo. S. Pearce wishes to know if there be any solvent for the sulphur stains in silver prints which are caused by allowing fingers soiled by hyposulphite of soda to touch the prints previous to toning and fixing. ——Answer: We are not aware of any.

"Is there any restriction upon the manufacture of changing-boxes for dry plates?—J. B."——In reply: We are aware of none. Among the numerous photographic patents obtained during the present year some may have been for apparatus of this nature; but particulars concerning these will only be ascertained after the specifications are published.

J. B. says:—"Kindly tell me through your columns what you consider would be the effect in a silver bath which has been neutralised before sunning with *ammonia* instead of carbonate of soda. Would it be likely to induce fog? (Of course it would be acidified before using.)"——In reply: Under such circumstances ammonia would not cause fogging.

"Kindly inform me which side of the stop to use nearest the focussing-screen. I have a lens fitted with a stop. One side of the stop has a bevelled edge. I have looked through several books on photography, and can find no reference to it.—A New Hand, Hanley."——In reply: The particular side is immaterial, but it may be safer to keep the bevelled side to the front.

"Will some one kindly advise me as to the best photographic apparatus to buy? I know nothing at all of photography, but want an apparatus to photograph any pretty views, also portraits of persons and children.—Ignorance."——In reply: "Ignorance" should first of all obtain a manual giving practical information in photography, and then place himself in the hands of one of the numerous respectable dealers whose business announcements are to be found in the advertising pages of this Journal.

Geo. Thompson desires to know the best method for estimating the amount of moisture in the atmosphere. He has been made aware of some peculiar class of hygrometer in which the indications are made by the rising and falling of a column of mercury, and would be glad if any reader could afford some information with respect to the construction of the instrument.——We pass on this query to our readers, merely observing that the recognised best method of ascertaining the hygrometric state of the atmosphere is by means of the wet and dry bulb thermometer.

T. S. S.—Our correspondent has been making varnish by the solution of shellac in alcohol; but he quite fails in getting it made clear. He would not mind a little colour, but it is essential for the purpose for which he intends it that it be quite limpid.——In reply: There are two or three ways by which he can get a limpid solution, one of them being by allowing sufficient time to the varnish to become clear. Of course there will remain a sediment at the bottom, from which the clear portion can be decanted. Recourse may also be had to filtration in order to cause the clarification of the solution. It has been recommended to mix finely-powdered chalk to lac varnish, and then to heat and filter it in order to obtain a solution of great purity and brightness. The proportions are stated to be equal parts of chalk and lac.

A. A. B. says:—"After sensitising the albumen paper I float it one minute on a fifteen-grain solution of citric acid; but as it gradually weakens how am I to find out its strength, so as to know how much citric acid to add to keep it about fifteen grains to the ounce after several sheets have been floated? The argentometer is no use in this solution."——In reply: If A. A. B. will make a fifteen-grain solution of citric acid, and carefully note its specific gravity, as shown by the argentometer, he has merely, in making subsequent trials, to see that the strength is such as to permit the argentometer to sink to the mark originally noted. By means of a few trials, and entries in one's note-book, the argentometer may be made useful in determining the strength of every aqueous solution made use of by the photographer.

"I shall be very glad if you will say in your *Notes and Queries*, next Friday, if there are any collodion dry plates (emulsion or otherwise) suitable for negatives, which can be developed like ordinary wet plates, now in the market. If not to be bought, will you kindly give a formula, and state approximately how rapid they would be?—A. H. B."——In reply: While we are aware of numerous formulæ for the preparation of collodion emulsions, the plates prepared by which are developed by pyrogallic acid, we are unaware of any that are suitable for iron development in the same way as wet collodion. We know, of course, that by immersion in, or being freely treated with, solution of silver nitrate, protosulphate of iron may be employed as a developer of dry collodion plates under certain circumstances; yet, so far as we have been able to discover, it is considered as being quite unreliable, and is not practised. We shall be glad to hear the experience of those who have tried it.

Simonides inquires if there be any definite rule for placing the horizon in a photograph.——Very much depends upon the nature of the subject. We should like our correspondent to state a case with more definiteness. If the query have reference to the placing of the horizon in a landscape background of a studio, then we should say that, although it *ought* to be on the level of the head of the sitter, it is not quite expedient that it be so, unless the composition of the landscape background be of that undefined class in which it is rather difficult to say with precision where the horizon is really situated. A horizontal line of a marked character should never bisect the picture in a line with the head, as it distracts attention from the face. But, while certain sacrifices may be made to conventionalism, the error must be avoided of carrying this too far, as in the case of certain American portrait and figure subjects, excellent in themselves, which were described in this Journal some time since, and in which the horizon line of the background was frequently as low down as the knees of the figures.

Concerning photo-enamels, J. Berryman (Redhill) writes:—"Some time ago you were kind enough to give me your opinion on an enamel I sent you. I promised to give you the result of my further experience. I discovered that the fault was not in firing: it was through the toning operation being defective. From what I hear and read I am convinced that three-fourths of the failures in this process are due either to an undue *thinness* of image or *incomplete* toning. Having now acquired, by nothing but hard practice for several months, some ability with this process, I can positively say that its supposed uncertainties and mysteries do not exist. As to the burning: it is simple enough. The *great* point to watch is the character of the film before toning, and so nice, to a point, must it be that no after-operation can in the slightest degree make up for the slightest imperfection in it. If my experience should at any time be of service to you I willingly offer it, and should do so the more cheerfully because I have suffered a good many days' experiment through the ungenerous misleadings of others."——We thank our correspondent for his kind offer.

Exchange Column.

Wanted a really good dark tent or carriage for dry-plate work. Excellent exchange offered, or cash.—Address, H., 365, Lodge-road, Hockley, Birmingham.

I will exchange a thoroughly-good microscope and slides for a light, whole-plate camera and double slides.—Address, A. BUGG, Stowmarket.

Tricycle—"Woodcock," Coventry, excellent machine, cost £25, valued at £15, for good tourist photographic apparatus, &c.—Address, TEAR, 12, Clapham-road, S.W.

A half-plate wide-angle landscape lens and 12 × 10 glass bath, with ground top, in exchange for a short focus *carte* lens.—Address, T. J. LLOYD, 2, Bailey-lane, Coventry.

What offers for a dark tent and tripod, for 12 × 10 (new), 10 × 8 wide-angle view lens, Photo. Stores' make (new), and Solomon's magnesium lamp.—Address, C. TAYLOR, photographer, Chislehurst.

What offers in exchange for a half-plate bellows-body camera, a quarter-plate Lerebours lens, camera, head-rest, and nine double printing-frames? Address, JAS. DRIVER, 65, St. Mathew's-street, Ipswich.

Wanted, instantograph or quarter-plate camera, &c., in exchange for books, or part cash. Offered, Tymm's *Wyatt's Art of Illuminating*, *The Sea, &c.*—Address, S. WELLS, Gladstone-terrace, Goole.

I will exchange a quarter-plate walnut sliding-body camera, two single dark slides, and a quarter-plate lens, by Shepherd, for a 12 × 10 water-tight glass bath.—Address, C. W. G. USHERWOOD, Tonbridge.

I will exchange *Photographic Almanacs*, for 1858, 1860, and 1862, and Delamotte's *Practice of Photography*, 1857, for a single landscape lens, six or eight inches focus.—Address, PHOTO, 3, Cicely-street, Edge Hill, Liverpool.

Wanted, bellows-body camera, 8½ × 6½, and Ross's rapid symmetrical lens, for 10 × 8, and Shew's eclipse shutter, in exchange for Dallmeyer's No. 2B ordinary, and well-finished modern oil-painting.—Address, J. MALINS, Crosswood, Aberystwyth.

What offers in exchange for Watson's 10 × 8 bellows-body square camera, latest improvements, two backs, two of Ross's studio cameras, Oborne's Eureka camera burnisher, and Watson's dark tent, all in first-class condition?—Address, BERLIN STUDIO, 440, Old Kent-road, S.E.

What offers for a capital half-plate portrait and view lens, double combination, six and a-half-inch back focus, in good condition? Wanted, a cabinet, or larger, rolling-press, with steel plate, in good condition.—Address, PHOTOGRAPHER, Oxford Studio, High-street, Cheltenham.

Wanted, a large-size porcelain dish, two or three lenses, by B. French, Boston, for Victorias, large-size rolling-machine, or offers, in exchange for England's drying-cupboard, backgrounds, interior and exterior, head-rests, grass mat, half-plate bellows-body camera, three dark slides, three cabinet lenses, and two and a-quarter ditto.—Address, J., 126, Bold-street, Liverpool.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

S. WELLS.—By advertising your special want you will no doubt meet with a response from several dealers.

SMITH (Manchester).—See report of the last technical meeting of the Photographic Society of Great Britain.

W. H. HARRISON.—We should advise you to give longer exposure. Perhaps you over-estimated the value of bright sunshine.

P. SPENCER.—The plates are not made now. We cannot undertake to send private replies, particularly when stamps are not enclosed.

SAML. JUTSUM.—There is a work by Husnik on the subject, but it is in German. You can procure it through any foreign bookseller.

B. WESTON.—You have used far too much glycerine. Refer again to the formula, and see if you have not misread "drachms" for "ounces."

W. E. G.—Any working optician will construct a lens that will answer your purpose as a condenser. The cost, we imagine, will not exceed a few shillings.

J. H. H.—The meetings of the Photographic Club are held at Anderton's Hotel, Fleet-street, E.C. The subscription is a guinea annually. Write to the Honorary Secretary.

TYRO (W.C.).—The plates have, without question, been exposed to light before they were developed. It is not a case of green fog, as you suppose, but fogging by the action of light. There is no remedy. Perhaps all the batch are not in the same condition.

STEPHEN RAWSON.—You are in error in saying that your communication of the 17th ult. was not replied to. If you refer to the Journal of March 21st you will see that it was answered. Surely you cannot take much interest in the matter about which you inquire if you do not take the trouble to look for the reply.

T. A.—We fear you will not be successful in removing the stains of wine from a photograph coloured with water-colours. The best plan will be to send the picture to the artist who coloured it in the first instance; he may possibly be able to help you in the matter by washing off the colour and repainting such portions as are defective.

J. H. L.—To utilise a portrait lens for views you must remove the back combination entirely and screw the front in its place—convex side next the ground glass. You will have to employ a small stop—say not larger than [illegible] or [illegible]; that is, if you wish for good definition over a moderate-sized plate. We cannot undertake to recommend any particular maker; that is against our rule. Every optician mentions in his catalogue the focal length of the lenses he supplies. From such data you will be able to judge which will be most suitable for your camera.

WALTER GRANT.—The tissue has clearly been kept in a damp place, and so has become mouldy. Its age will not, we think, affect its working qualities; but the mould doubtless will, by producing spots of insolubility, or, possibly, of different solubility to the other portions. However, it will not be much trouble to sensitise a piece and try how it works.

D. C.—The best plan is to treat the solution to recover the oxalate of potash. Add to the solution carbonate of potash until all the iron is precipitated; you will then have a solution of oxalate of potash which you can use again with fresh iron. We cannot trace the article to which you refer. There is one on a similar subject in our issue for 8th February.

WM. SELTH.—If you send negatives by the parcels post and they arrive broken you have no remedy. You cannot claim compensation from the Post Office. In future, if you continue to send through that channel, you must exercise greater care in packing. If you forward through a carrier, or direct by rail, and the package be labelled "glass," you can recover in case of injury.

PICKWICK.—The paper marked "B" has evidently been sensitised on too weak a solution, which is the cause of its yielding such feeble prints. This does not apply to the sample print marked "A," for the defect there is that the print has been much over-toned. It is clear that that sample of paper will not bear toning to the extent of the purple tones you require. This is a common failing with many of the ready-sensitised papers now in the market.

S. S. S.—No advantage whatever. Some operators in the wet collodion process used to prefer fused nitrate of silver to crystallised for preparing their baths; but we never heard it claimed for fused nitrate that it was better for printing purposes than the ordinary nitrate of silver. However, it is still an article of commerce, and you can procure a sample and try it for yourself. If your competitor's prints are so much brighter than yours it must be due to something more than the use of fused nitrate of silver.

RECEIVED.—Rev. T. F. Hardwich; George Smith. In our next.

THE LATE MR. J. H. DALLMEYER.—From the *Illustrated London News*, we learn that the will of the late Mr. Dallmeyer, the well-known optician, of 19, Bloomsbury-street, W.C., and of Sunnyfield, Hampstead-heath, who died on December 30th last, was proved on the 13th February, by Mrs. Elizabeth Mary Dallmeyer, the widow, one of the executors, the value of the personal estate amounting to upwards of £78,000.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday next, the 8th instant, at eight o'clock, in the Gallery, 5, Pall Mall East, when the evening will be devoted to an examination into the mode of preparation of lantern slides, and their exhibition with the Society's optical lantern (oxy-hydrogen lime light). Amongst others—illustrating the various processes, old and new—transparencies will be shown by Dr. Huggins, F.R.S. (astronomical), W. F. Donkin, F.C.S., F.I.C. (Alpine), and by R. Meldola, F.R.A.S. (scenes and natives of the Nicobar Islands).

GOOD FRIDAY.

NOTICE.—THE BRITISH JOURNAL OF PHOTOGRAPHY for the week ending April 11th will published at nine o'clock a.m. on THURSDAY next, the 10th April. Advertisements intended for insertion in that issue should therefore reach the Office by TUESDAY EVENING next, the 8th April. Small Advertisements will be received up to Nine o'clock on Wednesday Morning next, the 9th April.

METEOROLOGICAL REPORT.

Observations taken at 406, Strand, by J. H. STEWARD, Optician,
For the Week ending April 2, 1884.
THESE OBSERVATIONS ARE TAKEN AT 8.30 A.M.

March	Barometer.	Wind.	Dry Bulb.	Wet Bulb.	Max. Solar Rad.	Max Shade Temp.	Min. Tem.	Remarks.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1249. Vol. XXXI.—APRIL 11, 1884.

IMITATION OPALS.

As was stated in the previous article, the pigmented preparations there described may be used in connection with transparencies produced by the carbon, collodion, or gelatine emulsion processes. They may also be applied either before or after the production of the picture; that is, either as a substratum between the picture itself and the glass or as a covering to the picture. Obviously, the different circumstances thus developed necessitate modified modes of manipulation.

First, we will take the case of the application of the preparation in the form of a substratum. This is particularly well adapted for use with the carbon process, but it necessitates a perfection of substance which is not essential when applied over the picture—a perfection which is almost as difficult of attainment as a similar character in gelatine emulsion films. The difficulties are, in fact, identical in both cases, and consist in defects such as "pits" in the gelatine itself, dust and imperfections in the gelatine layer, as well as inequalities in the thickness of the film—all of which detract greatly, if present, from the beauty of the finished picture.

The last-named difficulties are merely mechanical, and are easily surmounted if a sufficient amount of care be devoted to the manipulations. The first, however, or "pits," is inherent in the gelatine itself; and if a tendency, however slight, to its production be present that sample of gelatine should at once be rejected. Fortunately for this purpose there need be no difficulty in securing a suitable gelatine which, so far as we are aware, is absolutely free from symptoms of pitting. This is secured in Nelson's No. 1, and, we have little doubt, also in other samples of pure English make. The softness of the brand mentioned is of less consequence for the purpose under discussion than it is in emulsion work, as an addition of chrome alum can be made to the baryta emulsion, not only without an ill effect, but with actual advantage in more respects than one. This is not necessary in the third method described, as the alum bath serves the double purpose of giving opacity as well as hardness to the film.

Glass of as even a surface as possible is chosen and well cleaned; the baryta preparation, very carefully filtered, is poured on to the depth of one-eighth of an inch, the plate having been previously accurately levelled. The thickness of the layer of gelatine will, of course, greatly depend upon the quantity of pigment contained in the emulsion and on the amount of opacity desired. If the emulsion itself be slightly tinted, then it matters not how thick and opaque it may be; but if it be intended to give a faint tint by backing with coloured paper, or if the picture itself is to be tinted by painting at the back, after the style of crystoleum, then a certain degree of translucency must be allowed. However, experience and a knowledge of the particular requirements will soon give the desired result.

The plate is allowed to set thoroughly, and is then transferred to a warm room or cupboard, free from dust, to dry, when it will be ready for use at any time. The surface should now present a perfectly smooth, matt appearance. The degree of deadness may be varied within certain limits by suitably arranging the proportions of gelatine and pigment respectively; but it is scarcely possible to obtain a glossy surface together with sufficient opacity.

When required for use the first operation is to wet the "enamel" surface, but the degree to which this operation is carried will depend upon the class of picture it is intended to superpose—in the case of a collodion picture the wetting being altogether dispensed with. The first effect of moistening the surface will be found to be an *increase* of the dullness caused by the rapid absorption of the water by the porous pigment. In a few seconds, however, the gelatine commences to swell, and gradually a more and more glossy surface supervenes.

Now if a carbon print is to be developed on the enamel surface the latter should be allowed to absorb a full quantity of water and to become quite smooth, the hardened gelatine forming a fine substratum for holding the delicate half-tones of the carbon image. If a gelatine emulsion is to be applied, then the water must be allowed to act no longer than is necessary to reverse the original deadening of the surface and cause the emulsion to flow evenly. If the wetting be omitted the emulsion will sink into the film unevenly; if it be too prolonged the sensitive film will be too long in drying. When a collodion film is to be applied the wetting must be omitted, but if, as will sometimes happen, especially with collodion emulsion, it sink in unevenly, a thin coating of india-rubber dissolved in benzole should be applied first and allowed to dry.

After fixing and washing in the usual manner the plate is dried and varnished either with thin spirit varnish or else a water varnish made by dissolving bleached lac in a boiling solution of borax. This gives great depth to the shadows without destroying the matt surface, and, moreover, forms a good protection.

In the case of a carbon print there is nothing special in the process of development; should any yellow bichromate stain be visible in the pigmented gelatine immerse in very dilute sulphuric acid. The development of either collodion or gelatine films must be as rapid as possible in order to avoid stains, and this necessitates, as a matter of course, that a full exposure be given. It is very desirable in all cases where pyro. and alkaline development is used that sulphite of soda or, better, sulphurous acid be also employed; if in spite of this precaution any stain accrue it will be necessary to remove it by dilute sulphuric or hydrochloric acid. The latter acid will also remove the yellow stain that may arise from iron development. However, these are simple matters to which the intelligent operator himself will see.

If the barium preparation is to be applied upon the top of a picture already developed—whether carbon, collodion, or gelatine—the operations are much simplified, at least so far as the obtaining perfect surface and freedom from stains are concerned. The glass selected should be as thin and colourless as possible, and in the case of gelatine negatives the films must be treated with chrome alum and dried before applying the barium emulsion; otherwise partial solution of the surface under the influence of the warm emulsion is probable. After drying, the back of the picture may be varnished if desired.

Very pretty effects are obtained with great ease by backing these pictures with suitably tinted papers, or by roughly colouring them at the reverse side of the translucent ground; but these are matters which must be left to the taste of the operator.

In addition to the hopeful effects, with very slight modification, he same barium emulsion may be used in connection with transparencies for window decoration. In fact, with the exception that a thinner coating of emulsion is required, very little modification is needful, and effects far superior to ground glass are produced.

LIME-LIGHT EXPLOSIONS AND THEIR PREVENTION.

In our issue of last week, when offering some suggestions respecting powerful lights that might prove substitutes, in some measure, for the lime light, we spoke of the perfect safety of the latter when placed under the management of competent individuals. We are personally familiar with the circumstances under which several explosions have taken place, and can most positively assert that in every instance they might have been prevented. It may seem harsh to associate with such mishaps either ignorance or carelessness, but to one or the other of these, in more or less mitigated association, they must all be relegated.

In the course of a communication by the Rev. T. F. Hardwich, in the present number—an article certain to receive the greatest attention from every reader interested in lantern proceedings—this gentleman offers various suggestions calculated to prove of great utility, and of which we recommend a careful perusal by every photographer. Mr. Hardwich, in a short letter which will be found in our usual correspondence columns, has also suggested that it might be well if some photographic society were to take this matter up, and offer a prize for the best safety tube and the best back-pressure valve. This, we suspect, would be of but little use unless some legislation were brought to bear on their employment.

We are tolerably familiar with many who are, in common *parlance*, "lantern exhibitors" or "dissolving view lecturers," but who never had an explosion during their lives, and who would, and do, pooh-pooh! the necessity or desirableness of any precautionary measures being taken. With such persons the precaution is axiomatic —"Keep your gas-bags properly weighted, and don't allow any interference with, or standing upon, your pipes, and you cannot have an explosion." This is a literal truth, but equally so is it a literal and unpleasant truth that, even with such persons, notwithstanding their knowledge of and intimate acquaintance with the conditions of safety, mishaps will and do occur.

A former editor of this Journal has placed it upon record that the requirements of a certain well-known professor of astronomy, who had had a narrow escape from an oxyhydrogen explosion, was something like the following:—"I want a burner that will give me a light of the very first order, but one by which an explosion shall not be possible by accident, by carelessness, or by design." The result of this was that our predecessor (J. Traill Taylor) invented and perfected a system of back-pressure valves, which so far fulfilled the intended purpose as not merely to have met with eulogium when introduced—at first privately, and afterwards more publicly through a communication to the South London Photographic Society in the beginning of 1868—but to have been made an article of commercial manufacture, and sold at a low price by leading scientific and commercial dealers of the period, namely, for instance, by Mr. Samuel Highley and the London Stereoscopic Company. But lantern exhibitors generally seemed to prefer saving the shilling or eighteenpence demanded for perpetual insurance money for the safety thus provided, and to run the risk. We are not at this moment aware of the precise sum at which these safety valves were sold; but we know it was a very small amount, for there was no restriction put upon the manufacture, the invention having been given to the public.

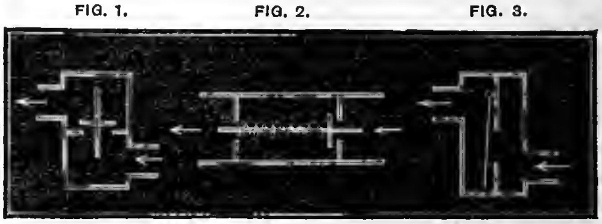
Conversing on this topic with our predecessor, he says, in effect, that the ignorance that prevails at the present time with regard to the terribly-potent mixed gases—oxygen and hydrogen—is such as ought to call for legislative interference with their free use, unless by those who can convince a competent examiner that they know at least something respecting the forces employed. "If I want to run and command a steam launch," he says, "on a stream, on which the travellers are exceedingly sparse, Government steps in and says that I must not risk my own life or those of my fellows until I shall have been examined by a competent authority as to my knowledge of steam and its effects, as developed in the yacht marine-engine, and why should not a similar test be applied to ascertain the competence of the individual who proposes to introduce a dangerous power in the midst of crowds of men, women, and children?" All this means, in plain English, that it is that gentleman's opinion that no one should be permitted to exhibit photographs or other pictures in public by the oxyhydrogen or lime light but those who, like the drivers of cabs or locomotive engines, are licensed to engage in such work. As regards this proposal we shall say nothing at present but this—that it would be certain to meet with strenuous opposition.

In the beginning of 1868 (for the particulars of which the reader is referred to THE BRITISH JOURNAL OF PHOTOGRAPHY for February 21st, 1868) Mr. Taylor brought before the notice of the South London Photographic Society the subject of explosions and the means of their prevention. We need not here recapitulate the arguments made use of on that occasion, or the conditions under which it was stated the mixed gases could with facility explode. It concerns us more at present to find the circumstances under which they could not explode. "If the weights on the bags," says the writer in question, "be not equally adjusted, the bag which is under the greatest amount of pressure has a tendency to transmit its gas to the other unless the orifice be sufficiently large to allow both gases to escape into the atmosphere. Should, however, the orifice be stopped by a particle of dirt, or by any other means, diffusion of the gases will take place with alarming rapidity." The foregoing, it must be admitted, is the positive side of our negative inquiry; but it serves to throw much light on the subject.

What is the effectual preventive of explosions caused by the back-pressure of either of the gases which, when mixed, form oxyhydrogen? Back-pressure or safety-valves—"only this and nothing more." The safety valve, which was introduced in consequence of the accident by which Professor Piazzi Smyth *might* have suffered seriously, even to the losing of his valuable life, is constructed on the principle that, concurrently with the withdrawal of the pressure caused by such an accident as the weight falling off the bag, a valve should close, and then the greater the drawback of the gases into the bag the more certainly would the valve act to prevent it.

In the following diagram an outline of three forms of this safety-valve are given. Nos. 1 and 3 are intended for insertion in the back of the lantern, flexible tubes or other fittings being "sprung" over

FIG. 1. FIG. 2. FIG. 3.



the two ends. In the first of these there is a seat upon which a very light valve rests, but which is thrown upwards upon the admission of gas, remaining up so long as there is any pressure of gas. If, by accident or otherwise, the weight were thrown off the gas bag, and the pressure of the gas thus withdrawn, the valve would immediately descend and close the passage through which the gas passed, rendering impossible the passage back of the flame beyond the safety-valve. *Fig.* 3 shows another way of effecting the same end. In it a flap is loosely hinged above an orifice in a plate which acts as a partition in the chamber. In its normal position it closes the orifice, but yields upon pressure being applied behind by the inflow of gas. *Fig.* 2 is different, and is intended to be inserted anywhere in the rubber tube between the lantern and the bag. What was effected in the previous two cases by gravity is in this one effected by a delicate spiral spring composed of a thin piece of brass wire, by which the valve is kept close as the normal position. The oxidation of these valves is prevented by giving them and their seats a thin coating of gold by the electro-metallurgic process. In some instances the flaps were faced with oiled silk, in others with thin leather and other pliant materials; but preference appears to have been usually given to metallic contact, precautions being taken to prevent particles of any foreign substance from getting access to the valves. The protection which they afford is, we are told, so perfect that when they are employed it is not possible, *under any circumstances whatever*, to cause an explosion, even when the most strenuous efforts are put forth to bring about such an occurrence.

This being the case, what is wanted, we imagine, is not so much a prize for the invention of an effective back-pressure valve as a means of inducing, or even forcing, lantern exhibitors to make use of them. There is no advantage whatever in looking for safety in the transmission of the gas through extremely fine apertures, such as those in tubes closely packed with wire or numerous folds of wire gauze, as the tenuity of the hydrogen flame is so great as to enable it to pass not only through these, but through porous wood. Indeed, it is on record that Mr. Gurney has sent the flame through a thin slab of plaster of Paris. Hence obstructive media of this class is of no use whatever, safety consisting alone in the employment of back-pressure valves.

LENSES FOR LARGE PORTRAITS.

It is pretty generally admitted that large portraits (within certain limits) taken direct possess certain qualities which, in the eyes of most photographers, are superior to pictures of similar dimensions produced by enlargement. Although, from a technical point of view, a large direct portrait—say a three-quarter- or half-length figure on an eighteen- or twenty-inch plate—if it be skilfully produced and with good appliances, may be better than an enlargement, it is, doubtless, within the experience of most professional photographers who have made this class of picture a speciality that, however perfect they may be, they frequently do not give entire satisfaction to the sitters; and, what is more, neither the sitters themselves or their friends can explain why or in what particular they are unsatisfactory. On this point we shall have something to say by way of explanation presently.

At a recent meeting of the Photographic Club the subject discussed was *The Best Lenses for Large Portraits with Gelatine Plates*. The decided opinion of all who took part in the discussion was that large and expensive lenses of the old portrait or Petzval type were no longer necessary, nor, indeed, in practice were they nearly so good as several other forms. The only advantage the old Petzval form of lens possesses over every other is its large angular aperture, upon which rapidity of action in all lenses depends, but with gelatine plates extreme rapidity is not so essential as it was with collodion. After all, the greater rapidity of large portrait lenses is more theoretical than practical. For example: if we have a lens of five inches in diameter, and we have to stop it down to three inches in order to obtain sufficient definition in the different planes of the picture, it at once becomes practically equivalent to a lens of only three inches in diameter, while the difficulty involved in its construction is immeasurably greater.

Now, having to stop down a five-inch portrait lens to three inches, particularly if it be one of short focus, is by no means an uncommon circumstance; even a two and a-half inch stop is frequently necessary to obtain a satisfactory result. Of course, stopping down to this extent necessitates a much-prolonged exposure, and the latter in the days of collodion had often to be measured by minutes rather than seconds. An exposure of from one to two, or even three, minutes was by no means uncommon with large lenses. Where, then, it may well be asked, is the utility of the large diameter, seeing that the full aperture cannot be used, and the difficulties in making large lenses are so much greater than with smaller ones? The only advantage is this: with the full opening, if the lens be a good one, small pictures can be taken with fair definition. Larger ones, too, can also be taken with a brief exposure, if we are content with definition in one plane only. This was often an advantage in collodion days, when the light happened to be indifferent and a portrait *had* to be taken. Now, with gelatine this advantage—and it is the only one such lenses possess—is not so great; therefore, lenses of smaller diameter are much to be preferred.

At the meeting to which we have referred the opinion expressed was that, for large direct portraits, lenses of the "universal" or "group" series, or those of the "rapid" type, are the ones most generally useful, and, for working qualities, are much to be preferred to the old portrait form. Single lenses were also well spoken of by some. In the selection of a lens, however, the professional photographer has to take into consideration which kind is likely to prove most advantageous under all circumstances. A single lens, if stopped down, will undoubtedly produce good portraits in the studio, and this is the cheapest form of lens to be had—no mean advantage, be it remembered. But single lenses must be employed in a good light, otherwise the exposure will be too protracted. Lenses of the "rapid" type, even when used with their full opening on a moderate-sized plate, are also very satisfactory for portraiture. But if a large plate have to be covered then diaphragms become necessary; hence in a dull light, or for portraits of children, unless very sensitive plates be used they may prove somewhat inconvenient. Certainly, in a good light and with plates of moderate sensibility they are all that can be desired.

The general impression at the Club appeared to be that, on the whole, lenses of the "universal" or "group" type were those to be selected. The only advantage, it may be mentioned, possessed by the "universal" over the "rapid" is the same as that which appertains to the portrait over every other form of lens, namely, its larger angular aperture, and, consequently, greater rapidity in working. It may thus be made available, if the light be bad, when other lenses cannot.

At the commencement of this article allusion was made to the fact that, however technically perfect, large direct portraits very frequently do not meet with approval from the sitter, and we are somewhat surprised that this point was not touched upon in the discussion. Here is, without doubt, a frequent reason: large portraits, as a rule, are taken from a point much too near the sitter. If they were taken from the same distance as is customary with *cartes* and cabinets they would, doubtless, prove as satisfactory as pictures of that size and the enlargements made from them. In taking these pictures, if they be "full lengths," the camera is usually placed from eighteen to twenty feet from the sitter, and if "three-quarter" proportionately nearer. For this distance lenses respectively of about eight and a-half and twelve inches equivalent focus are employed (the back focus, which is generally mentioned in catalogues, is considerably shorter than this); consequently, the longest diameter of the picture, in either, is considerably less than half the focal length of the lens, and the angle of view included is, of course, very narrow indeed.

It has been generally conceded that in order to obtain the most pleasing results in portraiture—both as regards perspective and artistic appearance—the longest dimension of the picture should in no case exceed one-half the focal length of the lens with which it is taken. In the *carte* and cabinet portrait this limit is not reached. But what do we find with lenses supplied for large portraits? It is a fact that, notwithstanding the greater difficulties in their construction and their necessarily lower degree of perfection as optical instruments, they are catalogued to take, and are actually employed to produce, pictures quite two-thirds—in some cases even more—the length of their focus. Thus, a lens of about twenty-eight inches equivalent focus (twenty-two inches back focus) is mentioned in the catalogues of some of our leading opticians as being suitable for pictures 20 × 16, and even larger. This is increasing the proportion to two-thirds of the focal length, and consequently a much larger angle is included, while the lens has to be approached very close indeed to the sitter; whereas to secure the best pictorial effects the picture, for such a length of focus, should not exceed fifteen by twelve inches. To take a picture twenty by sixteen, bearing in mind the rule just given, a lens of not less than forty inches equivalent focus should be used.

Although opticians have succeeded in producing portrait lenses which will cover a plate up to two-thirds, or more, of their focal length they should never be utilised to this extent if really artistic and satisfactory pictures be desired. We put forth this suggestion at the present season because the extreme sensitiveness of gelatine plates has induced many photographers to make a greater speciality of large, direct photographs than they have hitherto done

MINOR HELPS.

Seeing, as we do at times, so many faces, some strange and some familiar, their owners all anxious to know, and many willing to describe—whether faithfully or not we will not stay to discuss—the "latest thing out," we sometimes find a strong current of thought or opinion running in certain directions, enough at times to be worthy of prominence being given to it under a special heading. One topic that has become of passing interest in many quarters is the fatigue of developing operations in dry-plate work, so many operators and principals complaining of the extremely tiring labour of continually bending over the sink, watching and attending to the batches of negatives being produced as plate after plate remorselessly passes through the dishes of pyro. without break or pause.

In the olden days of wet-plate negatives the work was diversified in most cases by the operator taking up various kinds of manipulatory details—a plate to be coated, drained, and placed in the holder, then developed, intensified, and fixed, all involving a little action, if even limited in character, and in a fairly-bright light. But now it often enough happens that a good portion of the day is spent in exposing plates; then the development is all performed at one sitting, or standing, and dozens, scores, and hundreds of plates pass under the photographer's hands almost without the necessity for his once moving his position, the whole being carried on—at anyrate until recently—in a light of a most dismal character.

To meet this state of affairs, we cannot avoid thinking—and the opinions of many are with us—that the device of a portable and easily-removed seat, such as would be supplied by the adaptation of a bicycle saddle, as has been described in our Almanac, will become a common adjunct of the dark room of most photographers who care for their operators' comfort, or even their own. A bar and a strut with a bicycle saddle attached easily run under or from under the developing trough is too simple to be neglected, it might be thought. We heard rather a neat thing the other day *apropos* of this subject. The principal of a studio was discussing with his assistant (who also performed all the toning) this question of a saddle, and, asking for a suggestion as to the fixing of it, received this reply :—"A very good thing indeed, sir! Don't you think one would also do for the toning-room?

The care of the eyes, too, during the prolonged work of development is a really serious matter, and we have been glad to see it taken up from various points of view. There is no doubt that the selection of a light that shall give the greatest comfort and the greatest safety is a matter well worthy of all the time recently spent in public discussion upon it; but, whatever the light may be—daylight or artificial, canary, green, orange, or ruby—the eyes of the manipulator should be protected from the glare falling directly upon them. Some wear screens or shades, and others coloured spectacles; but the interposition of a sub-permanent screen that would hide the light from the eyes, yet allow it to fall unimpeded upon the plate, appears to us to meet the requirements of the case in a perfectly-effective manner. There need be little or no expense in connection with such an arrangement, and its adoption would at once tend to preserve the eyesight and assist in forming a proper estimate of the progress of the work—minute shades of differences in density or delicacy of image not being readily appreciable when the eye is subjected to the glare of a strong light.

The discussion on Willesden paper, held a few weeks ago, seems to be bearing fruit, and from many quarters we hear of an intention to test its qualities. So far, however, as it has been brought before our notice it is in the direction of its capabilities as a builder's material that it has appealed to the photographic mind. For such purposes it has real advantages, and we are informed by one gentleman that he contemplates making use of it for screening various portions of his glass roof during summer time at least, if not permanently. Its advantages for this purpose are obvious when it is remembered that a piece of galvanised iron or "corrugated zinc"—the material usually employed for small building alterations—weighs about ten times as much, area for area, as the Willesden paper. The latter, too, can be fairly readily cut up into pieces of any particular size required, while the corrugated sheets need a skilled workman to cut and fix them. The prices for the thickest "paper" and corrugated zinc of average thickness are almost the same, reckoning the superficial contents, while, as we have said, the weights are as one to ten.

Turning now to processes: we would call attention to Messrs. Robinson and Thompson's neat method of mounting adapted for large prints, as described in our number for March 21st. It is a variation of the method of applying the mountant to the damp print and allowing it to dry before attempting to place it on its mount; but in lieu of damping the latter—after the method described by Mr. A. Cowan some time ago—the print itself is again damped, though not sufficiently so to enable it to expand. The uninitiated might easily perform this part of the work sufficiently unskilfully to render the evil of cockling as great as ever; but to prevent this contingency occurring Messrs. Robinson and Thompson, who have had large experience in such work, have given a very succinct account of the method they have for years adopted with complete success—such success, they state, that even if the print were mounted in a book the "cockling" would be too insignificant to notice. As this is a point which we are frequently asked about we feel the greater pleasure in calling attention to this method. [*Vide* page 191.] While on this subject we cannot avoid calling attention to the greater frequency with which instances are brought before us of the distortion in portraits caused by the unequal expansion of the paper when wet. It is obvious that the method we speak of would to a great extent, if not completely, obviate its occurrence.

We would conclude the list of "minor helps" by again drawing attention to the plan we described a little while ago of immersing the developed plate, with little or no preliminary washing, into an acid solution of alum, using chrome alum in preference to the ordinary alum, on account of the smaller quantity required and the consequent increase in the rapidity with which it can be eliminated till a mere trace only remains. We have given it a fair trial, and are much pleased with the results. In the first place, we have found no perceptible disadvantage in entirely discarding the washing before aluming; and, secondly, even when plates have had a prolonged development we have found that the negative treated this way has, when fixed, little or no trace of the yellowness. Negatives finished in this manner have more wet-plate character than almost any other of which we have had experience. With the advent of warmer weather there is a possibility that a tendency to frill may be engendered. We trust not, and, meanwhile, shall be glad to learn from others their experience with this mode of treating negatives.

Mr. Cecil V. Shadbolt has quickly got his arrangements into form for aërial photography, and our readers will be interested to learn that the first ascents for the year of the "Sunbeam" are arranged to take place on Easter Monday and Tuesday, and we hope to be able to communicate at an early date full details of the success which, we trust, may attend them. Our readers will join us, we are sure, in wishing him a safe and successful journey.

Various chemicals have been recommended in our columns from time to time for drying-chambers, boxes for dry plates, paper, and soforth, and one or another has been pushed into notice as the best without any very logical cause for the preference. Owing to the researches of Herr E. Fleischer, however, a more definite value can be placed upon the various exsiccating matters employed, and an explanation given of their mode of action. His results, which we abstract, will be of considerable value to photographers. He says it is generally assumed that the air contained in a desiccator after exposure for a few hours to the desiccating substance is perfectly devoid of moisture. He made some experiments with a hygrometer, and found that sulphuric acid after a lapse of thirty-five minutes left thirty per cent. of the original moisture, after one hour eighteen per cent., and after one hundred and five minutes none at all. Calcium chloride after two hours left thirty-one per cent., after four hours twenty-five per cent., and after six hours twenty-one per cent. of moisture. These results are so very exact and conclusive that it is evident that chloride of calcium must be entirely rejected when quick and efficient exsiccation is required.

It may be remembered that Captain Abney, one of the examiners of the Council of the City and Guilds Institute, in his report last year, had to make some very depreciatory remarks upon the technical knowledge of the majority of the candidates in last year's examination. This year it is gratifying to learn that he says the results are much in advance of last, and that the past session marks a new era in the technical teaching of photography. We are not aware if it be possible for a student to gain a prize for photography who has never seen a camera, but we have heard of a prize being gained in a handicraft examination by a student who had no practical knowledge of the tools of the particular trade in question.

It is known that the late Duke of Albany was thoroughly *au fait* in photographic matters, as indeed all Her Majesty's sons are, and one of the last sad offices in connection with the interment was performed by photography, a negative being secured of the royal coffin as it rested on the bier under its crimson pall. Photography, in common with other arts and sciences, has lost a friend whose value will only be thoroughly appreciated now that he is taken from us.

Mr. G. A. Hahn has devised a sunshine recorder, differing entirely from those in use at the present time. It consists substantially of a retort exposed to the sun, and connected with a condenser and receiver placed in the shade, but in the open air. Bisulphide of carbon is placed in the retort, and a vacuum is made in the apparatus so that it may contain merely the vapour given off by the liquid. As long as the sky is overcast the liquid remains in the retort without distillation or condensation. As soon as the sun shines the bisulphide begins to boil, and the liquid collected in the receiver in a unit of time is proportional to the quantity of solar heat received in the same time.

The following method of testing the quality of glue, doubtless applicable in some respects for gelatine, is given in the *Tischler Zeitung*:—A weighed piece of glue (say one-third of an ounce) is suspended in water for twenty-four hours, the temperature of which is not above 50° Fahr. The colouring matter sinks, and the glue swells from the absorption of water. The glue is then taken out and weighed; the greater the increase of weight the better the glue.

A propos of the recent discussion on variously-coloured illumination for the dark room, in which singular differences of power in perceiving light by various experimentalists was shown, it will be interesting to make a note of a very elaborate series of experiments made by Drs. Kœnig and Dietrici, and communicated by them to the Berlin Physical Society. By means of an ingenious and elaborate arrangement these gentlemen caused minute sections of spectra to be placed in juxtaposition for relative comparison, and so to test the power of the observer's eye to detect slight differences of colour. Not to cumber the subject with too many details, we may say briefly that the results obtained enabled them to give three hundred as the number of differences of colour in the normal spectrum which the healthy eye could perceive. They observed three parts of the spectrum where the eye could appreciate differences with greater nicety. The position of the first of these maxima lay with a wave-length of 570 near the D line, a second greater maximum with a wave-length of 490 to 470 approached F, and a third smaller had a wave-length of 450 to 440. It was observed that beyond 640 and 430 these experiments could not be carried out; differences of intensity, but not of colour, could be discerned. This was particularly the case at the red end.

THE OXYHYDROGEN LIME LIGHT.

Few of your correspondents have had more experience with the lime light for lanterns than myself. For forty years I have lectured every winter and never had an accident. The accidents referred to in your article of the 4th instant were, I suppose, those in or near Bolton, and you will remember they were both caused by using ether for hydrogen. I have never seen the apparatus, but, as you know, ether is extremely volatile, the vapour often catching at a light several feet off.

But the ordinary lime light is of two kinds. The best for large pictures is that in which the two gases are mixed in a small chamber in the jet before impinging on the lime cylinder. This kind requires the use of two gas bags, and is perfectly safe provided equal pressure is kept on both bags. It sometimes happens that either people or articles of furniture cause the pressure-board of one bag to catch, whilst the other, of course, goes on. But this is manifest to the exhibitor at the moment by the light, and ought never to be allowed to continue to a dangerous extent. By increase of equal pressure this light may be made equal to pictures of twenty-five feet diameter. I have often had such in the large Town Hall of Ashton.

The second kind of lime light, and the best for pictures (say) fifteen or sixteen feet diameter, is formed by what is called a "blow-through" jet. In this jet the gases mix only at their exit from the tube, and cannot by any possibility cause an explosion. They are safer than any kind of paraffine lamp; for the heat caused by four or five wicks is intense enough, I should think, to volatilise the paraffine as dangerously as the ether above referred to. The blow-through jet requires only an oxygen bag, the hydrogen being supplied from the ordinary gas jet.

There is another very pretty little oxycalcium light (besides those in which alcohol in a spirit lamp supplies the hydrogen for the oxygen to blow through) which I invented many years ago, and used in my trinoptic lantern, described in Mr. Chadwick's interesting book on the *Magic Lantern*. It consists of a fountain argand lamp, having in the centre of the half-inch circular wick a small brass tube or jet of one-sixteenth or one-twelfth inch bore. This *feeds* the burning wick with oxygen and creates a small, white, intense light, which is again increased by the suspension of a lime ball half-an-inch in diameter by platinum wire right over the centre of the wick, which, becoming beautifully incandescent, unites with the flame and greatly intensifies it. This light is perfectly safe in any hands. The oil used is salad oil.

Now, one word as to the electric light:—My Rectory is lighted by it and I have a Gramme dynamo. But the electric light will only do for the lantern where the apparatus is fixed and permanent, as for large discs the *arc light* must be used. This is the case at the Crystal Palace. Incandescent lamps are seldom used of more than twenty-candle power. In these the *shape* of the light is bad for definition, and it is not sufficient for more than a small disc. Accumulators are as yet far from perfect, and it would require a very large number of them indeed to keep up an arc light for two hours. Depend upon it there is no light for the lantern equal to the oxyhydrogen lime light, and none more safe than the blow-through jet. St. Vincent Beechey.

SAFE LIGHT.

No. II.

There is no such thing known at present as a safe light. It is simply a question of comparative safety, and is in a very great degree dependent upon the manner in which the plates have been prepared.

I insist that any photographic plate prepared in absolute darkness has a certain amount of stability; that is, that it will bear a certain amount of exposure to actinic light, and still be able to resist the reducing action of any ordinary developer. If this were not so it would be impossible to produce a negative free from fog. The whole plate receives a slight general exposure to diffused light arising from two separate causes —reflection from the surfaces of the lens and reflections inside the camera. The first is far greater than is generally believed, but is very well known as the "ghost" or "flare" in certain cases. This is due entirely to light reflected from and between the inner surfaces of the lens, and gives the obnoxious flare spot in the form of a circular patch of considerable opacity in the centre of the negative. This flare spot is caused by the stop being at such a distance from the lens that the reflected image of the view in front of the lens only extends over a small angle. The amount of light which thus reaches the plate within this angle (through which the reflection is visible) is quite sufficient to fog the plate. The remedy is to alter the position of the stop until the reflected image is visible over as wide an angle as the plate subtends. The reflected image is always there, and consequently always acts upon the plate; yet a plate properly exposed shows no sign of fog, while one under-exposed cannot possibly be developed fully

If, therefore, it be granted that a photographic plate does, when carefully prepared, possess a certain amount of stability it is not difficult to believe that, unknowingly, this amount may have been lessened by preliminary exposure, not only during manufacture but in the various manipulations necessary before development can commence.

It must be borne in mind, too, that this preliminary exposure would have the effect of increasing the apparent sensitiveness of the plate. It will then, I think, be allowed that the greater part of the commercial plates must have had a very full share of this spurious sensitiveness, and that this must still be the case where coating and drying are not conducted in absolute darkness. It is quite impossible for all the operations to be done in the dark. For example: the plates must be examined for defects; but, as far as I can ascertain, the most reliable plates are those in which the working light is not only reduced to a minimum but the greatest attention is paid to the non-actinic character of the light, and also that the plate should only be exposed to this for as short a time as possible.

We now come to the question of what is the safest light, and to this only a qualified answer can be given. It was asserted at one time, some three or four years ago (but I cannot lay my hand upon the exact date), that when a plate had received a slight preliminary exposure to light, just sufficient to develope a stain, and that then the plate was exposed to the spectrum, while the blue end had a powerfully-actinic action the red end had a reversing effect, actually undoing the work which had before been done by light. Here, then, was the problem to solve: find a real red light, and it not only would be safe for working by, but would actually restore plates accidentally exposed. It would hardly have been a *safe* light for all that, for I expect we should have had complaints that the plates would not develope at all—that the red light destroyed the work done in the camera. Anyhow, it caused me to consider the subject and to experiment upon it; but, alas! only with the result of finding that, try whatever combinations I would, there was always some actinic light which found its way to the plate through every tone and depth of red I could procure.

The experiments themselves, however, were extremely interesting, particularly in the extraordinary differences in colours, which to the eye were very similar, and which were revealed instantly by the spectroscope. It was easy to understand how many of the deepest ruby tints were utterly unsafe, when, although the eye could not detect it, the spectroscope revealed the presence of a large proportion of blue. Now, without going deeply into the scientific question of colour, everyone knows that the blue end of the spectrum contains all, or very nearly all, the actinic rays, and that, consequently, blue photographs as rapidly almost as pure white. It is, therefore, self-evident that a "ruby" glass, which also transmits some of the blue, cannot be made safe by doubling its thickness; it remains absolutely the same. The surface must be extended to give the necessary amount of working light, when the same proportion of hurtful rays are present as would be from the less surface of a single thickness. The blue rays must be kept out, and, if possible, the yellow ones too; for why has bromide been employed in photography except for its greater sensitiveness to the yellow than iodide or chloride?

It is, therefore, utterly inadmissible that yellow of any kind can be a safe light, except under the conditions I have named, namely, that the plate is sufficiently stable to resist the action of even white light. This, too, fully explains the feat often performed of successfully developing a rapid bromide plate by ordinary diffused light. It is only a question of degree. The white is safe for a time, yellow for a very much longer time, and red for a still longer time.

It was clearly demonstrated a short time since, by Mr. B. J. Edwards, at the Photographic Club, that of two lights of as nearly equal illuminating power as could be ascertained, by the test of reading printed matter, the yellow had about four times the actinic action of the red. This fully confirms my own early experiments that the safest light is a red light, and that a light is only really red when the blue is entirely kept out of it. In practice this is easily done by the superposition of a suitable yellow. The red, which before allowed some of the blue rays to pass, is then noticed to have had a crimson tint. The addition of a yellow film alters the tone to scarlet; but while completely cutting off the blue it does not appreciably diminish the working light.

It becomes, therefore, more a question of personal appreciation than absolute safety. There are many people to whom a red light is positively painful. To such I would say—decidedly employ a yellow light, but do not for a moment believe it is, or that it can possibly be, safe. Look at it with the spectroscope and say if it can be safe; all the red, all the yellow, and all the green comes through. There is no such thing as a yellow light to be found unless it be in the spectrum, and even then it is very doubtful whether it is a simple or a compound colour. It certainly does not exist as a simple colour in any of the colours or pigments which pass by the name of "yellow;" for these, as far as I could ascertain, all contain an immense proportion of red. A most curious and interesting experiment to prove this is to take a piece of violet or purple glass and look at any yellow substance through it.

We will now speak "by the book," and I quote *Tyndall on Light:*—"This is purple because it destroys the green and the yellow, and allows the terminal colours of the spectrum to pass unimpeded. From the blending of the blue and the red this gorgeous purple is produced." What should happen, then, if we look at any object through a purple medium? Only the red or blue which happens to be present in the object looked at will be seen; any other colour will be absorbed by the purple glass. Look at the natural yellow. Take, for instance, a calceolaria and a scarlet geranium side by side; through the purple they are indistinguishable. Turn to the gravel path, to faces of your friends, or to the sunlit clouds, and everywhere that the eye sees a tinge of yellow this simple spectroscope shows a brilliant red. It must be existent there in what *we call* "yellow," or it could not be sifted out by the purple glass, which will allow none but red and blue to pass.

The weight of argument is manifestly in favour of the reddest possible light. Yellow would appear to be admissible only in the sense that its action is slow compared with white or blue light, while any shade of green as tending to cut off red and admit blue would appear to be the very worst of all. GEORGE SMITH.

NOTES ON THE LIME LIGHT.

[A communication to the Edinburgh Photographic Society.]

At the present season of the year the interest in the optical lantern begins naturally to decline; and yet, in one respect, it is a suitable time to write a paper, because the impression left by the winter's work is still fresh upon the mind. I venture, therefore, to communicate to this Society the following extracts from my note-book.

In the process known as the oxyhydrogen, or mixed gases, one-twentieth of an inch has been found to be a useful size for the orifice of the burner; but, as a biunial lantern consumes a large quantity of oxygen, I have tried this year to reduce it. I find that it may be reduced to one-twenty-fifth of an inch without much loss of light, but I still give the preference to the former size when economy is not an object. The actual size of the orifice, however, is not all which we have to consider; the distance inwardly before the bore begins to expand must also be taken into account. I lately purchased two burners, the nipples of which, when gauged with a needle, corresponded exactly in size of hole; yet one transmitted thirty per cent. more gas than the other in the same time, and gave a better light. On examination it appeared that the bore of this nipple measured one-twenty-fifth of an inch at the orifice, but, after passing inwards one-sixteenth of an inch, expanded to one-tenth of an inch; whereas the bore of the other extended three-sixteenths of an inch inwardly before it began to expand. On drilling the wide part of the latter lower down, it immediately transmitted the same amount of gas and gave the same light as the former. These nipples are sold at a low price—not more than one shilling or eighteen pence each—and hence it is a good plan, if you use a dissolving lantern, to purchase half-a-dozen or more and try them over until you find two to correspond. Platinum points are more expensive, but they are not necessary, as the brass points burn away very slowly and last a long time.

The distance of the point of the burner from the lime, measured diagonally, should be about a-quarter of an inch, when the angle of incidence is 45°. If you approach nearer, the dark cone of imperfect combustion in the centre of the flame will be apt to touch the lime, and, if so, a dark nucleus in the middle of the "spot" will be the result. The point of the nipple will also burn away faster, and will constantly be getting choked up with particles of lime; whereas, at a distance of a-quarter of an inch, it remains clean and bright. When the angle of incidence of the burning gases on the lime is less than 45°, the cylinder must be brought nearer. I have one burner, bent at an angle of seventeen degrees, which works best when it almost touches the lime. The flame then plays along the face of the cylinder, heating a large area and giving a very good light upon the screen.

I have quite discontinued working with very heavy weights on the bags, such as one and a-half or two cwts., finding the lantern more difficult to manage without an assistant, and the danger of accident greater. Abundance of light for all ordinary purposes can be got with three-quarters to one cwt. on an eight-foot bag, if the joints are gas-tight and the taps turned on full. I have never had an explosion, nor an injury from fire to any part of the apparatus, during an experience of many years; but I take certain precautions when working away from home, which it may be useful to mention:—1. Never allow any volunteers in the audience, who think they know "a little of magic lanterns," to come forward and help you. It often happens that they know less than they suppose.—2. Always strap on the weights to the pressure-boards, or tie them tightly with string; the "skeleton" boards, as they are called, are apt to roll over on one side during the lecture, and to allow one or both of the weights to fall off.—3. Place the boards at a sufficient distance from the wall so that they cannot touch it in their descent, and put a reliable person in charge of them, with strict injunctions to allow no one to come near.

I have spoken of very heavily-laden bags being difficult to manage, but a further objection is that you cannot so easily get a noiseless flame if you go beyond the three-quarters or one cwt., especially when the orifice of the burner is small.

Other causes of "roaring" or "humming" are as follow:—1. A roughness in the bore of the nipple, and usually in the narrow part of the bore near to the point. Polish the interior of the bore by rotating a needle in it with your finger and thumb.—2. The two gases present in the wrong proportions; an excess of hydrogen will make a humming noise, which on turning on a little more oxygen will disappear.—3. Atmospheric air, either in the hydrogen or in the oxygen. The effect of this is well seen in an ordinary house-gas jet, which roars on first lighting it, until all the air is burnt out; also, in Broughton's ether tank, which does the same.—4. The mixing chamber too small or altogether absent. What we call the "mixing chamber" is useful, although some have said to the contrary, and if it be suppressed you will find it hard to get a silent flame—especially so in the "ethoxo" process, since ether vapour does not mix with oxygen so easily as coal gas. When any impurity—such as common air or nitrogen—is present in the gases the flame will often roar during the whole of the lecture, unless you work with a large mixing chamber.—5. The plug of the dissolver is sometimes a cause of this defect. The two gas passages in it may not be equal, and the hydrogen may begin to pass before the oxygen. A roaring noise will then be produced at the orifice of the burner *during the dissolving*. File away a little of the oxygen groove and the noise will cease.

Whilst on this subject of "dissolving," I may allude to the snapping noise, like that of a percussion cap, which occurs with some burners of the blow-through kind, when there are two concentric tubes, and the outer tube of hydrogen projects beyond the inner tube for the oxygen. I thought at first that it might be remedied by turning on a larger by-pass hydrogen flame, or by altering the plug of the dissolver so as to give the advantage to the hydrogen. It was suggested to me, however, as more effectual, to throw a little oxygen into the by-pass flame, and this I found to answer perfectly. It acts by keeping the base of the flame at the outlet, and by not suffering it to sink back into the chamber beneath; but you must use only a small quantity, or the lime will become incandescent in the lantern which ought to be dark.

I strongly advise that all dissolvers should be made with a by-pass tap to both gases; for, even in the oxyhydrogen process, a little oxygen in the by-pass is very useful in keeping the lime of the dark lantern red hot, and thus preventing it from cracking when the blow-flame returns. The dissolving is also better, since the slightest touch of the handle makes the lime incandescent and brings in the second picture.

Manufacture of Oxygen Gas.—I have a word to say on the use of chlorate of potash for preparing the oxygen. There is a difference in the ease and rapidity with which the oxygen mixture gives off its gas. The last sample which I had was purchased from a good London house, and labelled "pure recrystallised," but it required a stronger heat than usual to decompose it. I was advised to apply to Messrs. Kurtz, of St. Helens, Lancashire, who are manufacturers, and have a good practical knowledge of the subject. They suggested that the quality of the oxide of manganese might make a difference, and sent me two samples—one containing eighty-three and the other ninety-three per cent. of real oxide. Black oxide of manganese is a mineral found native in Devonshire, and varies much in percentage of $Mn\,O_2$, moisture, and hardness. After experimenting with different samples, I am inclined to think that the kind which breaks with a conchoidal fracture and is very hard to pulverise is the most suitable; but there is probably something not yet clearly made out, because the chlorate of one crystallisation supplied to me by Messrs. Kurtz appeared to give off its gas at a lower temperature than the pure recrystallised, with the same sample of black oxide.

Broughton's Ethoxo Lime Light.—When coal gas is not available I still continue to use the ether process invented by Mr. Broughton, of Manchester. From letters received I gather that ether vapour is thought by many to be a more explosive substance than hydrogen or coal gas. Such, however, is not the case. The experiments of Sir Humphrey Davy and other chemists have shown that coal gas mixed with atmospheric air and ignited, explodes with ten times less violence than hydrogen gas, and that ether vapour will not explode with air. It will explode strongly, however, with oxygen in the right proportions, which have never been correctly determined, but are said by some to be six, and by others ten, volumes of oxygen to each volume of ether vapour. The "detonating line," if I may be allowed the expression, is very narrow, and an excess of oxygen on the one side, or of ether vapour on the other, prevents the explosion from taking place.

An opinion also exists that the ethoxo lime light is altogether more powerful than that of hydrogen or coal gas, but I have not been able to verify this in my own experience. With me there is practically very little difference between the three; but if I were asked to arrange them, it would be in the order before given, namely, hydrogen, coal gas, and ether. I should place hydrogen gas first in its power of producing incandescence of the lime when mixed with oxygen.

In Broughton's tank the ether is not vaporised by heat, but a small quantity of oxygen is passed through it. This constitutes a source of danger, because an explosive mixture might be formed if the disengagement of ether vapour were not sufficiently copious. The oxygen should be *saturated*, or nearly so, after which the mixture will burn like common gas. Mr. Broughton seems to have studied this part of his subject carefully, and I have received from him tanks with horizontal septa, in which the oxygen travels through more than a foot of ether, and others with vertical septa, where it passes over as much as six feet of ether.

Any of the above tanks will answer the purpose, but it is obvious that, through defective soldering in the manufacture, they might possibly fail, and pass the oxygen by a much shorter route than that above indicated. Or, supposing the apparatus to be right, the ether might be wrong, and in either case a simple and reliable test of efficiency promises to be useful. Such a test is found in the *colour* of the flame. When you have purchased a tank fill it with the lightest methylated ether of ·720 sp. gr., and light the flame at the jet of the lantern. If it burn yellow and luminous, like the flame of a candle, the proportion of ether will be sufficient to give safety. So much for the general directions; but now allow me to go into particulars, because this test, when properly applied, is as good as an analysis.

To study the colour of the flame effectually it is not enough to turn on the tap gently and to allow it to burn against the face of the lime. The lime would impart to it its own colour, and, therefore, must be taken out of the way. Close the O tap of the jet entirely, and put on a strong pressure from the H tap of the jet until the flame shoots out, like a blow-pipe flame, to a length of six inches. You will then notice one of three different stages indicating less and less ether, before the last or explosive stage is reached.

1. In the first stage, when the ether is plentiful, the flame is yellowish, with an outer envelope of blue most marked at the base and point, the blueness being due to oxidation by the surrounding air. This flame, when allowed gently to play upon the lime cylinder, does not heat it red hot, except at the edge of the flame, but sometimes deposits carbon upon it.

2. With a smaller quantity of ether in proportion to the oxygen the interior yellow flame dwindles away, and the outer envelope of pale blue becomes more and more pronounced, until the flame is blue throughout with an edging of violet next to the air. This flame will heat the lime to bright redness, but it will not make it glow. By turning off the tap suddenly you find that it is not explosive; for it dies away like common gas, and at last goes out without passing back into the mixing chamber beneath.

3. In the third stage the outer envelope of violet has encroached upon the blue, just as the blue before did upon the yellow, and the whole flame is of a fine violet tint, fringed with a dull red or purple. It will now heat the lime to whiteness and make it shine, but not with the full degree of incandescence. It cannot be termed very explosive, because if you turn off the tap it goes out quietly. I am not prepared to say, however, that it could not be sucked back or forced back into the mixing chamber; but, if so, my knowledge of the subject teaches me that the explosion would probably be an extremely-rapid combustion rather than an explosion properly so-called.

4. In this last stage there is not a very material difference in the colour of the flame, which is still a shade of violet; but *the cone of imperfect combustion* at its base, which you can easily see projecting from the point of the jet, is *very much smaller in size*. Instead of being three-quarters or one inch long, as it was before, it has diminished to a quarter or one-eighth of an inch, and if you find this you may be sure that there is danger. When you turn off the tap the flame will pass at once into the mixing chamber with a sharp report. You will, perhaps, say —"Will it not pass still further and blow up the ether tank in which it originated?" Let me explain that I have taken the precaution beforehand to affix to the jet a small pumice chamber supplied to me with the tank, and the flame on reaching this can go no further. I will say a few more words on this subject.

Back-pressure valves—whether made of metal or silk—however good for arresting the flow of gas, are, according to my experience, useless for stopping flame. If you fill a small india-rubber balloon with explosive ethoxo gas, and place it behind one of them, the gas will burn at the mouth of the lantern jet as long as the contraction of the india-rubber keeps up the pressure; but as soon as the balloon is nearly empty the flame will rush back through the whole length of the jet and through the valve, shattering the balloon to pieces. The pumice safety chamber, however, is more effectual, and I have filled the same balloon five times running, and fired the gas with a loud report, without any other effect than shaking the pumice and pulverising a part of it, the balloon on the far side remaining intact.

My advice, then, to persons holding crowded exhibitions is to procure two of these pumice chambers, to have them properly tested, and to place them—one upon the H nozzle, and the other upon the O nozzle of the tank at the end nearest the lantern. In addition to this a back-pressure valve may be put on the O nozzle of the tank at the end furthest from the lantern to prevent suction if a weight were to fall off the bag; the protection will then be complete. The tank itself has a reserve chamber, so that no back suction or forcing of *ether* into the bag would be possible; but it would not be wise to subject the best of safety arrangements to the strain of a suction backwards. In attaching the tubes be careful to use only the thickest and best india-rubber. Ether exerts a solvent action and softens the commoner kinds, which speedily give way and produce leakage.

The principal inconvenience attending the precautionary measures I have suggested is that they lessen the pressure of the gas, and, consequently, the intensity of the light. In the first tanks sent to me by Mr. Broughton, with horizontal septa, I could not use them on that account; but in the last tank received from him, which has vertical septa, the pressure is so strong that I can overcome these obstructions and still get all that I want, with no more than one hundredweight on the bag.

Two questions have still to be answered:—Can the ether be used over and over again by simply making it up to its original bulk with fresh ether of ·720? To test this point I took five fluid ounces of ether which I had put away in a bottle as having been too often used to be reliable, and, after filling it up to eight ounces with ether of ·720, I poured it into a tank made to hold fifteen ounces. On passing the oxygen the flame burnt yellow, but slightly inclining towards blue. In half-an-hour it burnt pale blue, and in another half-hour violet. Then, in another quarter of an hour the gurgling noise in the tank became irregular, indicating that the ether was evaporating down almost to dryness and that the last of the septa had been reached. On turning off the tap the flame went out quietly without explosion, and the tank when weighed was found to contain exactly three fluid ounces of ether. This experiment speaks for itself; but, to make assurance doubly sure, I shall still continue to reject what remains of the ether after using it a certain number of times in the tank.

But an objector may raise another difficulty. He may say that the lecture room is sometimes very cold, and this would be likely to hinder the volatilisation of the ether. To find how far depression of temperature affects the result I took two of Broughton's tanks—one with horizontal and the other with vertical septa—filled both with methylated ether of ·720, and placed them in a vessel containing ice. After leaving them for six hours in a cool cellar well wrapped up with flannel I brought them in the pan just as they were, in their flannel jackets, and connected them with the lantern. Both burnt at the jet with a blue flame, having a small kernel of yellow in its centre, and worked much in the usual way, excepting that less oxygen was required at the O tap of the jet to render the lime incandescent. This result was better than I anticipated, for I had great fears beforehand that the ether would not rise sufficiently at a temperature of 32°, and that the only effect of passing oyxgen would be to fill the tank with explosive gas.

The Oxygen Bag as a Source of Danger.—This bag has been known to take fire more than once, even in the blow-through or safety process, and the cause is supposed to be an accumulation in it of a dusty or powdery substance produced by the disintegrating action of chlorine present in the oxygen as an impurity. With the experience we have of the burning of flour mills, and ignition of coal-dust in mines, it is reasonable to suppose that this powder would burn with extreme rapidity if any flame were allowed to travel backwards into the bag. I would suggest, therefore, that a back-pressure valve should be placed on the nozzle of the bag when such a substance is known to be present. After long use, however, my own bag is quite free from powder, and the only precaution I take is to thoroughly purify the oxygen. Pass it through two washing-bottles, the long delivery tube of the second being closed at the end and then perforated with a number of small holes, like what is called a "rose burner." Fill each bottle three-quarters full of solution of common washing soda in the proportion of a-quarter of a pound to the pint of water, and the oxygen will then be nearly or quite free from smell. No water will enter the bag if four or five feet of india-rubber tubing of half-an-inch internal diameter be used to connect it with the nozzle of the second purifier.

Since my last communication to this Society I have seen a small screw regulating tap, invented by Messrs. Oakley's assistant. It seems to me likely to be useful in preventing accidents, both in the oxy-hydrogen and in the ethoxo lime light.

I have also adopted the "Excelsior" limes of Messrs C. and F. Darker, Forest Hill, London, as giving the best light of any which I have tried. They are sufficiently hard and very well centered.

After I had finished my "notes," and made them almost ready for the printer, I saw a report of the disastrous explosion at the Chadderton Town Hall, and of the evidence given by Professor Roscoe. He entirely condemns the use of the ethoxo light, but allows that he has had no practical experience of it. If he had tried it I think he would have come to a different conclusion.

The cause of the Chadderton accident was undoubtedly the forcing of a little ether backwards into the oxygen bag from absence of a reserve chamber, which ought to have been provided. The same thing, in substance, has happened more than once with the mixed gases. A weight has fallen off one of the pressure-boards and the expansion of the gas in consequence has sucked back gas from the other bag. I think the confidence of the public will not be fully restored until back-pressure valves and safety tubes are brought into more general use.

I have also within the last few days seen an account of an accident at a magic lantern entertainment, where the mishap was said to be caused by a rent in an india-rubber tube. Now it may seem at first that a rent in the tubing would not be a very serious matter—that it would simply allow a free escape of the gas to which the tube belonged. But if you consider for a moment you will see that it would also allow *a return current of the other gas*, and that the two would mix at the point where the tube was injured, instead of in the mixing chamber of the jet.

T. Frederick Hardwich.

MEASUREMENTS IN LANDSCAPE PHOTOGRAPHY.

Every lover of landscapes as depicted by the aid of photography must at times have felt how interesting it would be to have at the foot of the view, or somewhere convenient for reference, an account of the dimensions of the important objects included, as well as the distances of hills, mountains, and other natural objects that form the background of the picture. Most artists take care to have a man or some figure of a known height near the object to be specially brought out, so that the eye of the observer at first glance may form an idea of its proportions.

If by some simple apparatus the actual measurement, or a close approximation, can be readily obtained, I venture to think that a short time would be spared to each picture for the necessary observations. I propose, in the following remarks, to touch upon those instruments suitable for the purpose:—1. For showing inclinations and vertical heights.—2. Distances of objects in a direct line from the observer.—3. Horizontal angles and the distance apart, of different objects. Under the first head will be considered instruments that show altitudes by means of atmospheric pressure, by instruments showing degrees out of plumb or level, and by reflection. Of those that show by the weight of the atmosphere the aneroid barometer is the only one that need be seriously considered, as its accuracy when well constructed is such that differences of ten feet of ascent or descent can be at once seen. It is portable and not likely by fair usage to get out of order; whereas it is quite an undertaking to carry about a mercurial barometer. The aneroid will be found a capital travelling companion, both as a weather glass and altitude instrument—heights of *accessible* places being taken by simply setting the zero of the altitude scale at starting, opposite the hand, which will fall or rise as you ascend or descend from the level, and show at sight the number of feet. In hilly and mountainous scenery this is very interesting.

For inaccessible objects, or those hills that would require arduous climbing, a clinometer of some form is very useful, and generally the most available. These usually fold up so as to be portable, and have the sight separated as far as possible consistent with their construction, so that the eye may preserve a straight line when looking at the object. The lower portion of the hinged limb has a small spirit level inserted in it, so that the observer may see he holds it or places it on the camera-stand correctly, and then while doing so he raises the upper portion of the limb until the cross sight intercepts the object. An arc shows the degrees of inclination, and there is a supplementary table showing the rise in inches per yard horizontal. It follows that if the distance between the observer and the object be known it is easy to find out the height. Example:—26 degrees = rise of eighteen inches in each yard. If the distance from the base of the object be thirty yards, the height will be $1\frac{1}{2} \times 30$ = forty-five feet.

Several convenient forms of clinometers are made—some as folding rules six inches long and some are square or circular boxes, nearly all having compasses attached so as to take horizontal angles, as explained hereafter. Of the clinometers those with pivoted compasses are the best, and for a clinometer compass the one in a flat, square mahogany box approved by the professors of the School of Mines is a really practical pocket companion, as it gives degrees of inclination, general slopes, rise in inches per yard, and degrees of magnetic bearing.

Regarding a reflecting instrument; the most portable is the box sextant; but, while it is a most useful instrument for surveying, it requires too much time for the purposes of photographers; as all the calculations have to be worked out by trigonometry, and in most cases an artificial horizon (of mercury or perfectly flat glass) must be used.

A very simple method of determining the height of an inaccessible object when no instruments are at hand is the following:—Fix a staff of a known length (one of the legs of the camera extended will do) in the ground facing the object (tree, spire, tower, mountain top, &c.) to be measured, retire until the top of the staff agrees with the top of the object, measure the distance between the staff and yourself and the object and yourself, and, as you know the height of the staff, it is only necessary to multiply it by this proportion of the two to get the height of the object. Example:—Height of staff, five feet; distance from observer to staff, ten feet; and of observer to object, sixty feet.

The proportion being one in six, it is only necessary to multiply the five feet less the height of the eye from the ground (say three feet when kneeling) by six feet to get the answer. The rise being two feet in every ten feet run. The distances should be paced twice, and the mean taken to ensure the approximate accuracy. This plan is often used by military men.

To Determine direct Distances from the Observer and also Distances Apart of Different Objects or Horizontal Angles.—An instrument of a very ingenious character has been designed by Major Poste, and carried out by Mr. J. H. Steward, optician, Strand, London, to enable an observation to be made quickly and give distances, *without any calculation whatever*. The advantage of this is that not only can different angles be found, but considerable time saved when measuring the height of an object by its inclination from the observer. It is of moderate size, occupying about the same space in its sling case as a full-sized binocular glass, and, with the addition of sights, &c., suggested by the writer, it forms an admirable clinometer. All that is necessary to measure the distance of an object is to lay out a short base at right angles, and with the instrument to reflect the staff at the end of the base on the object. As soon as this is done the distance is shown by means of a cleverly-calculated arm intersecting a curved line. Any length of base can be used, and distances of 8,000 yards readily taken. The base can be measured before or after the observation, and the instrument is provided with an optical square, so that a perfect right angle may be laid out and the assistant or staff (the camera stand will do) placed at the apex of the angle.

Supposing it is desired to know the distance apart of two inaccessible or distant objects, it is only necessary to measure the distance of each object from the observer. Take a proportionate part of that distance—say one-tenth or one-twentieth—and place staffs at these points in a line with each object. If the distance between these two staves be measured, and it is multiplied by ten or twenty, as the case may be (that is, the proportion used), the distance between the two objects will be found. The widths of rivers, mountain gorges, &c., can also be ascertained by this instrument, and for those observers who care to go scientifically into surveying they can do with it all the work of the box sextant.

There is one great point with the mechanical calculator attached to the macrometer—that the divisions are units of the measurement employed; so it follows that, whatever the base is measured in, the distance will be given in that measurement. Yards, metres, chains, &c., can be employed at will. This instrument has been exhaustively tried by Her Majesty's Government and found very accurate. It has also been highly approved of by a number of engineers, surveyors, and military men. Being of strong make it is not likely to get out of order.

The photographer has at hand in his camera stand a capital rest for the instrument, and also, as explained, the means of making a staff to use when judging heights or distances. I am aware that some gentlemen do take with them on their tours a pocket barometer, and here and there a clinometer; but I hope the above may be interesting, and at a future time useful, to a number of your readers.

To get Angular Distances.—The compass attached to the clinometers or the macrometer can be used. The easiest mode of fixing the relative position of objects is to show their compass bearings, and then from that find the observer's own position on the ground. This can be done by taking bearings of two or more points and laying down the back bearings from those points. The point of intersection shows the spot of observation.

The compasses have check stops, so that the card or needle may be brought to rest and locked when the sighting vane intersects the object. The number of degrees shown by the compass for one object is subtracted from that of the other when the angle is registered.

G. R. Baker.

NOTES ON THE LIME LIGHT.—ON THE REV. T. F. HARDWICH'S PAPER.

[A communication to the Edinburgh Photographic Society.]

Being favoured with a sight of the above paper, I gladly add a few remarks which occur to me. As regards the light from jets, those I have most used have been only 1 mm. (one twenty-fifth) in bore, and I get with these ample light for a disc sixteen feet in diameter. But in discussing these matters I feel the want of a standard to go by—slides differ so, and some are satisfied with so much less brilliance than others. The personal element we cannot check; but I beg to suggest that it would be a good thing if some society would prepare and issue a "standard slide," of which copies could be had printed to one uniform density and transparency. We shall never get the most perfect jets till we have some such standard, to be cast upon a sheet of a given diameter. I think the best plan for the internal bore is to use a "broach," such as watchmakers employ, which is *very slightly* tapered—almost imperceptibly. Then, if a slightly-tapered steel wire be scored longitudinally with coarse emery paper, the bore can be beautifully polished at any time by turning it round. At one-eighth inch from orifice the taper should be widened. Much, however, depends upon the *outside* of the nipple, which should be nearly a knife-edge, and as thin as possible. The nipple I send, made from the point of a Wilson stylus pen, is not finished inside, but outside represents my idea of what a nipple should be, and, it will be seen, casts much less shadow than most nipples would do.

The only point I rather question is as to distance from the lime. Mr. Hardwich, I think, reckons his "angles" with the surface itself. So reckoned, I prefer about 35°, which keeps the nipple from *casting a shadow* when of proper shape. But with most nipples, on trial, I find more light the nearer the orifice, and the practical point seems determined by the distance needed to avoid clogging up. With larger orifices the distance does get greater. I begin with one cwt., and as pressure gets down put on half-a cwt. more to finish; but I certainly find more pressure, up to the capacity of the orifice, gives more light within at least certain limits. You do not, however, get light in proportion to extra gas. The best jet I know is one brought out by Mr. Place, of Birmingham—I believe in answer to my own pressing in part. It has the great merits of cheapness, and raising the lime the proper distance at each revolution. It was this latter I so much urged upon him some time ago.

I, too, find "excelsior" limes the best, and especially in accuracy of form. But of late, urged thereto by Dr. Maddox, so well known for his interest in photomicrography, I have turned my attention once more to oxide of zirconium. Within a short period lately, while absorbed in the adjustment of lenses for the lantern-microscope, which I have been working at for some time past with encouraging results (the proboscis of a blow-fly can be well shown on a screen from six to twelve feet long), I have cracked three condensers through omitting to turn the lime. I find the oxide can now be procured considerably cheaper than formerly, and I have just purchased an ounce to endeavour to make into pencils. Dr. Draper's experiments, to which Dr. Maddox kindly referred me, seem to show that the two great points are—first, exposing the oxide to intense heat for some hours before working up, during which heating it shrinks considerably; and, in the second place, to avoid all agglutinating material, but to make up with a little water only by the aid of great pressure. A pencil so made, which needs only be about one-quarter of an inch diameter by half-an-inch long (heated by the jet at one end) would probably be too fragile for ordinary lecturer's use; but, if it can be obtained, would be very valuable for scientific work, even if not really "indestructible." I should be very glad to hear from any one disposed to attempt its manufacture.

Like Mr. Hardwich, I think the "skeleton" boards very unsteady. I never use them, preferring plain boards, with a hinged double leg at one end, and a hinged stay or stretcher which ties to it. The support is the full width and cannot slip; and when the gas is half gone the stretcher unties and the boards go down on the floor. A patent has lately been taken out for a support which runs on castors and needs no adjustment whatever, the feet being in a rigid line with the top board, projecting in front; but of course this needs more floor space.

It is impossible to say too much in favour of the double washing of oxygen with soda. Not the least advantage is that you do just as well with common chlorate at 7½d. to 9d. per lb. I only now use about one-fifth of manganese, and find the gas comes off much faster, so that I often get the bag filled in twelve or fifteen minutes; indeed, the difficulty is to avoid a "rush" of gas. A little experience guards against this; and as for safety the india-rubber Woolf tops I use for wash-bottles are each a safety-valve against mere pressure.

In regard to the ether light: one main point in my opinion—and here I differ very seriously and strongly from Mr. Broughton's printed directions—is to turn on the hydrogen tap from the tank *first* so as to *vent all pressure* from the ether vapour. It is that which is the great source of danger; and this can be absolutely prevented. But while, on the one hand, I share Mr. Hardwich's profound regret that Professor Roscoe should have condemned indiscriminately and wholesale a process he admittedly knew nothing of (and, if I am not mistaken, even the mixed gases have exploded in Owens College, as a gas bottle, said to be so "safe," has done at the Royal Institution, and repeatedly in America), on the other hand I do not think anyone can use the ether light safely who has not *clearly before his mind its two special dangers*, and their reasons and their method of prevention. They are—first, the risk of want of saturation; and, second, that of "back-pressure." I do not think a few brief directions, and the statement that all is safe if these are followed, gives that *impression* to an operator, and I would urge more detailed instructions very strongly. Mr. Diggle, at Chadderton, evidently had not the faintest real conception of the very serious danger when he found ether in the supply-tube. I believe it was in the bag as well. He thought that when he had "poured it out" and the jet lit, all was right. The fact was, as I believe, that at first the oxygen far outweighed the vapour as regards *oxygen*-supply (and it was the bag which exploded). But by degrees the oxygen in the bag got exhausted, while the ether in the bag (I cannot understand the bag catching fire unless ether was in it) *still evaporated at the same rate*, until at last it was bound to reach the exact explosive point. That is my reading of it after the evidence.

All this attaches great importance to the new pumice safety-chambers. If they stand exhaustive testing they will be a great boon and comfort to many. Hemming's packing has failed, so has Gurney's water safety-chamber, and gauze is a sheer delusion; while anything that pretends to be "safe," and is not, is obviously more harm than good, since reliance is placed upon it which there is nothing to justify, and other care which might prevent accident is neglected. But a *bonâ-fide* safety arrangement is another thing; and I hope Mr. Broughton's pumice-chambers may ere long receive sanction which cannot be disputed. LEWIS WRIGHT.

LECTURES AT THE ROYAL INSTITUTION.

PHOTOGRAPHIC ACTION.

THE last lecture of the series was given on Saturday last, the 5th instant, before the same audience which have attended the other lectures. A commencement was made by referring to the different modifications of the molecular kinds of bromide, and the conversion of the green form into the orange form by mechanical pressure. The colours of the two kinds were very well seen, as they were exposed side by side in the lantern, which, by-the-bye, has been ably presided over during the course by Mr. C. Ray Woods. Various photographs taken with the invisible rays were shown on the screen, and then the lecturer passed on to consider the rays which were potent in causing the reversal of the photographic image. He showed that an image of the carbon points thrown through red glass on to a sensitive plate which had been exposed to light, and then treated with bromide of potash, caused a destruction of the action, and further emphasised the fact that not only red rays but blue rays were equally efficient by showing that the entire spectrum apparently undid the preliminary exposure The image was developed on the screen and turned out successfully.

A short account was given of the history of photography in natural colours, commencing with Seebeck's notice of the colouration of chloride of silver in 1810. The labours of Poitevin, Niepce St. Victor, Simpson, and St. Florent were briefly alluded to, and the experiments made by the lecturer were also described. According to Captain Abney the colours are due to two or three kinds of molecules, which are oxidised molecules of silver sub-chloride. The impression of colour was much more rapidly taken by the sub-bromide or violet-chloride in the presence of all kinds of oxidising material—such as bichromate of potash, peroxide of hydrogen—whilst in the presence of those substances which could take up iodine, bromine, or chlorine, the production of colour was impossible. The lecturer exhibited spectra in natural colours on paper, on gelatino-chloride, and on daguerreotype plates. In the second the colours were readily seen by transparence, showing that they did not result from interference.

The spectra on the daguerreotype plates were fairly brilliant in the blue violet and green violet, and the red was clearly marked. The lecturer stated that a mixture of the red and blue molecules would give a green molecule, and that these were probably similar in composition but different in mass, thus giving rise to difference in colour. The existence of orange, blue, and green forms of molecules in bromide of silver were adduced as exemplifications of the possible existence of more than one form of oxidised molecule.

The audience examined the examples of colours with marked interest. The possibility of photography in colours in the future was discussed, and the advent of such a possible process insisted upon if earnest workers in the field would but put their "shoulder to the wheel." The effect of dyes on films was then experimentally demonstrated, and in a photograph of a coloured plate it was shown that the use of cyanine blue made the yellow nearly as actinic as the blue. The principle that the work done on a sensitive plate corresponded with the absorption of the particular rays was further insisted upon experimentally, and three slides of spectra were shown, exhibiting the fact that some sensitive salts could themselves act as sensitisers to others. With this our readers are familiar, so we will not enter into the arguments the lecturer adduced at this part of the subject.

The clock at this point struck four, and it should have marked the termination of the lecture, but it was evident from the shoal of diagrams which were hung that Captain Abney had by no means exhausted the subject-matter of his lecture. He kept his audience a few minutes, however, in showing them one problem which required solution, and which, as it is novel, we give for the benefit of our readers. That the lecturer had a partial solution of it we believe, but time did not permit him to enter into it. A disc of cardboard, on which were pasted black strips as given in the diagram, was made to rotate very rapidly on a whirling stand, and to the eye, where the indentation in the star at A and B took place, a thin, dark circular line was visible instead of a lighter one, which would naturally be expected. To the eye the effect might be due an optical illusion or to some physical phenomenon connected with the eye; but a photograph showed that the white ring would be photographed when the rotating disc was set in motion, and that, therefore, it was not subjective.

On another disc, with the star showing white spurs on a black background, the lines at A and B were whiter than the adjacent spaces instead of darker, as would be expected, and these also showed in the photographs. This concluded the lecture, and brought the series to a termination.

PHOTOMICROGRAPHY FOR BEGINNERS.

[A communication to the North Staffordshire Photographic Association.]

AS some of our members are ardent microscopists as well as amateur photographers, perhaps a few remarks upon using the camera and microscope together may prove useful, and should anyone profit thereby, even though only in a slight degree, it will give me great pleasure to have done what has lain in my power to assist him, and if possible to transfer to other persons my own ardour in this interesting branch of our art, the practice of which, unfortunately, my rather weak eyesight will not allow me to pursue.

In the first place, all that is necessary for the production of photographs from microscopic slides is a good microscope, a camera of quarter- or half-plate size, and a good lamp giving a steady flame. I have in my practice used a microscope by Matthews—an old-fashioned one with plenty of metal at its base, giving it a firm stand, and one which is capable of being placed in a horizontal position. The camera, an ordinary bellows-body one, is joined to the microscope by removing the eyepiece of the latter and the lens of the former, and placing the camera, with microscope attached, so that when the lamp (this is one flame) is placed behind the condenser the rays of light will pass straight through the whole affair, and fall exactly in the middle of the ground glass. You can fill up the interstice between the microscope and camera-front with anything suitable, such as a silk handkerchief wrapped round the brass tube; or it would, of course, be a better plan to make a camera front specially fit the microscope tube.

Having seen that the lamp, light, condenser, object-glass, tube, and centre of ground glass are all in one plane, you may commence operations with any suitable slides. In the first beginning, use a one-inch or half-inch power and practise with it until sufficient experience is obtained to warrant your proceeding to a higher power. When practicable, it is as well, or better, to use a low power and get a sharp negative; this, of course, may be afterwards enlarged by the lantern to any reasonable size. This enlargement is made upon argentic enamel paper from the accompanying negative of *Saccharina lepiscua*. I do not know how many diameters it is enlarged, but you will see that one of the animalculæ is now the size of the whole of the microscopic slide, glass and all. You will also see that this "enamel" paper is very suitable for such a class of work as this, on account of its freedom from apparent granularity.

The slides with which I have worked have been almost all injected and stained histological specimens. They are about the worst subjects one could choose as a beginner, on account of their brown and red colour. The specimen photographs which I hand round will show that the most successful are from slides which have had no staining operations performed on them, such as crystals, &c., &c.

The slides should be prepared expressly for photographic purposes. If sections, the thinner they are cut the better; in fact, they cannot be cut too thin. Be content with a half-inch objective first, fasten the slide in its place, and, having adjusted everything as above directed, cover your head and the camera as usual with a cloth, and focus first with the coarse, and afterwards with the fine, adjustment. It is as well to remove altogether from the camera the piece of ground glass, and replace it by a piece of plane glass which has been coated with a solution of white wax in benzole and allowed to dry. This will give a much finer and more suitable surface for the purpose than ground glass. When focussed as sharp as possible the dark slide and slate may be inserted and the exposure commenced. This will, of course, vary with the nature of the subject, and can only be judged by practical experience; but by using a stand and light, such as an ordinary argand petroleum lamp, after a few trials the necessary exposure may soon be judged. By the way, in focussing, and using a half-inch objective (never mind the same not being corrected for colour) with artificial light, and getting as sharp an image as possible on the screen, it will come out sharp on development. As to development: I prefer Audra's ferrous oxalate, for with it perfect control can be obtained, and should a plate be slightly under-exposed it may remain any length of time in the solution without fog, as in forcing with pyrogallic acid.

Again: should intensification be necessary do not use the mercuric iodide and hyposulphite intensifier. Some of these were treated with it, and they are almost useless now; whereas, had they been left alone, they would have been nice, thin negatives, from which transparencies could have been obtained. As regards the kind of plates most suitable for use with the microscope: do not use a quick plate—such a plate as is suitable for landscape work. One containing a fair proportion of iodide to bromide will give the best results, and be the most serviceable for use with artificial light. The exposure will vary from ten minutes to two hours, so there is plenty of time to meditate and smoke a pipe during the operation; and, as the development is done but slowly, one plate may be exposed while another is developed. For any other information I will refer you to the excellent articles which have lately appeared in the technical journals. W. B. ALLISON.

ARTIFICIAL IVORY.

IN the following specification of a patent, by JARVIS BONESTEEL EDSEN, of Adams, Mass., U.S.A., we have a means whereby tablets of artificial ivory suitable, *inter alia*, for photographic miniatures may be prepared.

THIS invention relates to the manufacture of artificial ivory from xylonite or a cellulose compound.

The object of the said invention is the production of an article which closely resembles, and is adapted for use as, a substitute for ivory.

The said invention consists essentially in forming a composition chiefly of such substances as xylonite, or those elements which are formed chiefly of pyroxyline.

According to the present invention I form the xylonite or its equivalent substance of different densities, and in some cases of slight differences in colour, and cut the same into sheets, by any of the well-known processes for such manufacture, and then combine them in the said sheet form by rolling or pressing them together under great pressure, so as to compact the several sheets into one entire mass, but in such a manner as to preserve the peculiar characteristics of the structure of each sheet, and at the same time make such a compact body that, when cut into thin sheets, the various sections in the said sheets will show the different characteristics or grain of the original sheets of which the mass was composed, and thereby imitate the various growths or laminated character of the ivory.

It is evident that this composition and combination may be made of various materials and in various manners without departing from the nature of this invention.

Having thus fully described the said invention and the manner of performing the same, I wish it understood that I claim—

First. The method of forming artificial ivory or a substitute for ivory, by forming the material for the several growths or layers of xylonite or similar substance of different densities or different characteristics of composition; cutting the same into sheets, and then compressing the several sheets of all the elements into one entire mass; and making into sections the several layers as by the process of cutting, for producing the sheets to imitate ivory as hereinbefore set forth.

Second. An artificial ivory or substitute for ivory formed of xylonite or similar compound, the basis of which is pyroxyline, so as to resemble ivory, substantially as described.

PRODUCING PRINTS OR TRANSFERS OF PHOTOGRAPHIC PICTURES.

THE invention of Mr. Eugenio de Zuccato, of Charterhouse-street, London, in the direction indicated by the above title, has been of such a comprehensive nature as to have induced him to embody it in three separate specifications. It will be seen that they all relate to the utilisation of the Woodbury relief as a means of producing surfaces capable of giving prints in fatty inks. As these specifications follow each other in immediate succession in the patent records we shall adopt the same order.

No. I.

MY invention relates to an improved method or process of producing prints or transfers of photographic pictures, and is carried into practice in the following manner, that is to say, I take what is known as a "Woodburytype relief" of the picture which it is desired to print or transfer, and I lay this relief upon a sheet of paper or analogous material, placed on a slab or plate (such as those hereinafter described) having a smooth surface which is inked with printers' ink so as to form a grain, stipple, or series of closely-assembled lines or dots; I then press the said relief, the paper, and the slab or plate together by suitable mechanical means, whereupon the printers' ink will more or less completely "set off" and be impressed on the paper or analogous material, and thus form a grained, stippled, or lined picture or ink-photo. print corresponding to the said "Woodburytype relief." This grained, stippled, or lined image or picture may then be transferred to metal or lithographic stone by any method known to printers; or the grained, stippled, or lined image or picture may be photographed and a transfer made therefrom by any method known to photolithographers and photozincographers.

The term "Woodburytype relief" is well understood by photographic printers; but to prevent any misapprehension I desire to state that I mean a gelatine film in which the varying tints of a photograph are represented by varying thicknesses of gelatine, or a substitute for the said "Woodburytype relief," such as a cast or mould.

The materials which, for the purposes of my invention, I regard as analogous to paper, are such thin, flexible, or yielding materials as will readily take an impression in printers' ink. Among these may be mentioned tracing-cloth, ribbed or grained transfer paper, tin or other foil, gold-beaters' skin, silk fabric, or other suitable tissue.

To explain what I mean by "a slab or plate having a smooth surface which is inked with printers' ink so as to form a grain, stipple, or series of closely-assembled lines or dots," I quote the following as examples, viz.:—

(1) A lithographers' stone upon which a stipple or lined ground of any kind is imprinted.

(2) A zinc plate upon which a stipple or lined ground of any kind is imprinted.

(3) A slab of any kind upon which a tint or stipple in printers' ink has been inscribed or transferred.

(4) A slab or sheet of paper, either enamelled or plain, upon which a tint or stipple in printers' ink has been impressed, inscribed, or transferred.

By the term "printers' ink" I mean any ordinary printing ink in which a pigment is incorporated with an oily vehicle, or similar fatty inks such as are especially made and sold for the purpose of transferring. When I re-photograph the ink-photo. print I sometimes use an ink of which the vehicle is glycerine, mucilage, or a similar substance.

Soft wax, fat, varnish, soap, or a mixture of these materials may, in some cases, be used in place of ink when the image is to be transferred to stone or metal.

Having thus fully described my said invention, and the manner of performing the same, I wish it understood that I claim—

The production of a picture or transfer by pressing paper or analogous material between a "Woodburytype relief" and a slab or plate lined, grained, or stippled with ink, substantially as described.

No. II.

MY invention relates to an improved method or process of producing prints or transfers of photographic pictures, and is carried into practice in the following manner; that is to say, I saturate or ink a piece of fine network or other textile fabric either with printers' ink or with a transfer ink such as is used by lithographers, care being taken that none of the meshes or ribs of the fabric are blocked up with ink, but that each rib or thread is well saturated. This inked fabric is placed in contact with a sheet of paper; and either upon the said paper or upon the inked material I place a "Woodburytype relief," and the whole is then subjected to pressure by suitable mechanical means.

I can so vary the working of my invention as to ink the "Woodburytype relief" itself; but in this case the paper or analogous material must always be placed between the relief and the fabric. The pressure causes the ink to "set off" from the inked material on to the paper, upon which is thus formed a picture in a kind of stipple corresponding to the "Woodburytype relief." This stippled picture is then either transferred to metal or stone by any method known to printers, or it may be photographed, and a second transfer in fatty ink made, by methods known to photolithographers and photozincographers.

I can, if desired, so practice my invention as to obtain the grained or stippled image directly upon a plate of zinc or other metal, or upon a lithographic stone. For this purpose I first lay the inked fabric upon the plate or stone; I then place the "Woodburytype relief" upon the said inked fabric and apply pressure by suitable mechanical means as above described.

Fine wire gauze may, in some cases, be used in place of the textile fabric, and I may mention silk gauze, ribbed silk, ribbed or grained transfer paper, and bookbinders' cloth as examples of the fabrics I use, such fabrics as are thin and yielding or flexible being best adapted to the purposes of my invention.

The term "Woodburytype relief" is well understood by photographic printers; but to prevent any misapprehension I desire to state that I mean a gelatine film in which the varying tints of a photograph are represented by varying thicknesses of gelatine; or a substitute for the said "Woodburytype relief," such as a cast or mould.

Those materials which, for the purpose of my invention, I regard as analogous to paper are such thin, flexible, and yielding materials as will readily take an impression in printers' ink. Among these may be mentioned tracing-cloth, tin or other foil, gold-beaters' skin, a collodion pellicle, silk fabric, or other suitable tissue.

By printers' ink I mean any ordinary printing ink in which a pigment is incorporated with an oily vehicle; or similar fatty inks such as are especially made and sold for the purposes of transferring. When I re-photograph the ink-photo. print, I sometimes use an ink of which the vehicle is glycerine, mucilage, or similar substance.

Soft wax, fat, varnish, soap, or a mixture of these materials may, in some cases, replace ink, when the image is to be transferred to stone or metal.

Having thus fully described my said invention, and the manner of performing the same, I wish it understood that I claim—

First. The production of a picture or transfer by pressing an inked textile fabric or the like against paper or other suitable material by means of a "Woodburytype relief," substantially as described.

Second. The production of a print or transfer on paper or analogous material, which is pressed between a textile fabric or the like and an inked "Woodburytype relief," substantially as described.

No. III.

MY invention relates to an improved method or process of producing prints or transfers of photographic pictures, and is carried into practice in the following manner; that is to say, I take what is known as a "Woodburytype relief" of the picture desired to be printed or transferred, and I lay this relief upon a sheet of paper or analogous material, and on the other side of this paper or other material I place a roughened, grained, stippled, or lined plate which has been inked on its roughened side with printers' ink. The roughened side of the plate must be next the paper or analogous material. I then press the said relief, the paper, and the inky roughened plate together by suitable mechanical means, whereupon the printers' ink will "set off" or be impressed on the paper or analogous material, and thus form a grained, stippled, or lined picture or ink-photo. print corresponding to the "Woodburytype relief." This grained, stippled, or lined image or picture may be transferred to metal or lithographic stone by any method known to printers; or the grained, stippled, or lined image or picture may be photographed and a transfer made therefrom by any methods well known to photolithographers and photozincographers.

The term "Woodburytype relief" is well understood by photographic printers; but to prevent any misapprehension I desire to state that I mean a gelatine film in which the varying tints of a photograph are represented by varying thicknesses of gelatine, or a substitute for the said "Woodburytype relief," such as a mould or cast.

Those materials which, for the purposes of my invention, I regard as analogous to paper are such thin, flexible, or yielding materials as will readily take an impression in printers' ink. Among these may be mentioned tracing-cloth, tin, or other foil, gold-beaters' skin, silk fabric, or other suitable tissue.

By a grained, stippled, or lined plate I mean a plate of any moderately-hard material of which at least one surface is roughened, grained, or lined. As examples I may, on the one hand, mention a metal plate or block of wood which has been grooved or stippled, a cast of this plate or block in ebonite, dry gelatine, or celluloid; and, on the other hand, a sheet of emery cloth, sand-paper, or bookbinders' cloth.

By printers' ink I mean any ordinary printing ink in which a pigment is incorporated with an oily vehicle; or similar fatty inks such as are especially made and sold for the purposes of transferring. When I re-photograph the ink-photo. print I sometimes use an ink of which the vehicle is glycerine, mucilage, or a similar substance.

Soft wax, fat, varnish, soap, or a mixture of these materials may, in some cases, replace ink when the image is to be transferred to stone or metal.

Having thus fully described my said invention and the manner of performing the same I wish it understood that I claim—

The production of a picture or transfer by pressing paper or other suitable material against an inked roughened plate, or the like, by means of a "Woodburytype relief," substantially as described.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The usual monthly meeting of this Society was held on Tuesday last, the 8th inst.,—Mr. James Glaisher, F.R.S., President, occupying the chair.

As had been previously announced the meeting was devoted to the exhibition, by the Society's lime-light lantern, of slides prepared by various methods for comparison of the results thereby attained.

Mr. T. Sebastian Davis, who had acted as Chairman of the Committee appointed to arrange the business of the evening, prefaced the exhibition by observing that photography had come into very general use for the production of slides for the lantern, and that for many subjects—but especially for architectural ones—photographs were much to be preferred to even careful hand-drawings: because details were represented that could not—in such a small compass as lantern slides—be drawn in by the artist, and in some subjects the details really gave the character to the whole. The various photographic processes that had been employed for the purpose—wet collodion, collodio-albumen, dry collodion, Woodbury process, gelatino-bromide, and gelatino-chloride—were referred to by Mr. Davies, who went on to say that he had many years ago struggled with the difficulties attending dry collodion for this purpose, the chief of which was that the plates, when prepared, would not keep. The introduction of gelatino-bromide had removed this difficulty, and the plates prepared by this process appeared to keep indefinitely, and, at the same time, gave much greater rapidity than before was obtainable; but, having perfected the negative process, we come now to the production of positives. Transparencies of a very high character—perhaps even the highest of all—had been obtained upon wet collodion. The difficulty with gelatino-bromide has been that the high lights were apt to be more or less veiled. Sometimes perfectly clear prints could be obtained, but not with certainty. The search for this perfect clearness had culminated in a process which is a very slow one—the gelatino-chloride: but this slowness is no disadvantage for the particular purpose now under consideration.

A series of slides made by wet collodion in the camera, the work of Mr. P. M. Fincham, from a variety of subjects, including views of Ilfracombe, Brixham, Tynmouth, Plymouth, and Clovelly were first shown.

Mr. F. Howard's slides, of somewhat similar character, were next projected upon the screen.

Mr. Meldola's slides, also upon wet collodion, were then exhibited. They excited much interest, as being records of the expedition sent to the Nicobar Islands in 1875 to photograph the eclipse of the sun.

Mr. C. Ray Woods then showed a series of slides, made upon wet collodion and toned by the ferrid-cyanide and uranium intensifying process, and by modifications with iron and copper suggested by this process. Some of those toned with copper, also with uranium and a trace of iron, were very rich. The iron alone gave a blue tone, which, however suitable for some special subjects, would not be likely to find general acceptance; whilst, when uranium was the only metal employed, the tone was warmer than—except as a particular fancy—would be desired.

Mr. W. England showed some slides made in 1860 upon wet collodion, upon coffee plates, and upon tannin plates. Of these the wet collodion were rather the finest. Some collodion slides, by Mr. England, of statuary subjects, were also shown. In these there was a black background surrounding the figure, with curtains at the top and sides. Coloured sheets of gelatine were used to give a glow to these curtains.

Several slides by the Woodbury process, sent by the Sciopticon Company, were next exhibited. Amongst these were some beautiful slides from microscopic objects, foraminiferous shells, and diatomaceæ.

A series of slides of Swiss scenery, by Professor F. W. Donkin, were then exhibited.

Mr. Moncrieff next showed a number of slides produced upon commercial gelatino-bromide plates, and developed with sulpho-pyrogallic.

Mr. J. B. B. Wellington exhibited a series of transparencies produced upon gelatino-bromide plates developed with Mr. J. B. Edwards's ferrous oxalate formula for chloride plates, with and without the addition of bromide of potassium as a restrainer. One of these, without the restraining bromide, was of a clear, pure black tone; whilst with the bromide the slides varied in colour, according to its quantity, through brown up to a claret colour. Three plates of a mill at Corfe Castle, developed in the different ways mentioned, showed the beautiful variety of tones obtainable.

Slides of Dr. Huggins's negatives of star spectra, and of the eclipse of the sun of 1871, were next exhibited.

Mr. B. J. Edwards showed slides printed upon albumen, and toned with gold and hypo. Some of these were very rich and fine; but Mr. Edwards said that equally good results could be obtained upon gelatino-chloride with much less trouble, and that was the process he should recommend.

The Chairman—in proposing votes of thanks to the exhibitors, to the committee, and to Mr. J. Cadett for the management of the lantern, which were carried by acclamation—said that, after all, wet collodion held its own very well, and, at all events, need not hide its head before the most recent productions of the art.

Mr. Robert Tindall was elected a member of the Society.

It was announced that at the next ordinary meeting, on the 13th of May, Mr. J. Spiller would read a paper *On Fading*, and Mr. W. E. Debenham one, accompanied by demonstrations, *On Illumination of the Dark Room.*

The meeting was then adjourned.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held at the house of the Society of Arts, John-street, Adelphi, on Thursday last, the 3rd instant,—the Rev. F. F. Statham, M.A., F.G.S., President, occupying the chair.

The minutes of the previous meeting having been read and confirmed, Mr. A. T. Tagliaferro, of Malta, was proposed, and duly elected a member of the Society.

The Chairman then made the presentation of the silver medal given by the Society in connection with its monthly competitions for the best picture of the year. On this occasion the medal fell to the lot of Mr. F. A. Bridge for his excellent picture, *A River View*—a scene on the Thames. In making the presentation the Chairman took occasion to remark that many very artistic pictures were to be obtained in and about London if they were, as had been done by Mr. Bridge, carefully selected and then artistically treated. He quoted instances where most unpromising-looking subjects had been really artistically rendered, yet perfectly true to nature, in some of the illustrated periodicals, simply by judiciously selecting the point of view.

It was announced that at the next meeting Mr. Norman Macbeth had kindly consented to read a paper on an artistic subject, and members were requested to introduce a friend at that meeting, as the paper, from Mr. Macbeth's well-known ability, would doubtless prove a very interesting and valuable one, as that gentleman had devoted so much attention to the art aspects of photography.

Messrs. C. and F. Darker then gave an exhibition of objects in their polariscope lantern. Before commencing the exhibition,

Mr. C. Darker concisely explained to the meeting the principles of the polarisation of light and the use of the Nicol prism, illustrating his remarks by projecting sections of the tourmaline, Iceland spar, selenite, &c., upon the screen. Space will not permit of our reproducing Mr. Darker's remarks, but those who desire information on the subject of polarised light are referred to a leading article on page 145 of our issue for the 4th ult. A chameleon, several flowers and various designs, formed of selenite, were then thrown upon the screen, and the analyser being rotated caused the colours produced to change, and a most pleasing effect was produced, exciting considerable astonishment in those not familiar with the phenomena of polarised light.

Passing from what may be termed the more popular portion of the subject, Messrs. Darker exhibited specimens of rock crystal, showing a "cross crystallisation" which at times causes considerable inconvenience to opticians in the construction of "pebble" lenses. These defects, though not visible by ordinary light, were rendered very manifest when it was polarised. Various crystals—such as salicine, benzoic acid, santonine, our old friend (or enemy?) hyposulphite of soda, citrate of soda, tartaric acid, &c.—were next shown. A very interesting feature of this portion of the exhibition was the formation of crystals of boracic acid. A slide, upon which was a concentrated solution of boracic acid, was introduced into the lantern, and the salt allowed to crystallise. The display under the polarised light was very interesting. Next the effect of pressure on glass was demonstrated. A plate of glass was secured in a frame in such a manner that pressure could be applied to one edge at will by means of a screw. Until the pressure was applied the glass was perfectly transparent and free from colour; but immediately the pressure was applied brilliant colours were produced, which gradually disappeared as the pressure was removed, clearly demonstrating the effect pressure had in altering the molecular condition of glass. The effect of heat in altering the molecular state of glass was also shown. Different rock sections were next exhibited; and, finally, several photographs of various crystalline substances, produced by Mr. George Smith, were projected upon the screen. These pictures showed the advantage which would often accrue if certain objects were photographed in both kinds of light. Several of the slides exhibited, it may be mentioned, were kindly lent for the occasion by our contributor Mr. Lewis Wright.

The CHAIRMAN, in proposing a vote of thanks to Messrs. Darker for their interesting and instructive demonstration, remarked that photographers were inclined to look to the practical rather than the theoretical phases of the subject, and suggested that polarised light might be made available for detecting impurities or adulterations in the materials they employed. In doing so he directed particular attention to the effect produced by pressure and heat upon glass as demonstrated by the polariscope, and also pointed out that the working qualities of photographic lenses might be materially influenced by their being secured too tightly in their cells, so that greater pressure was exerted upon one portion of the glass than another. He (the Chairman) said that, however much might be read upon the subject, nothing could convey an idea of the effects of polarised light like a demonstration such as they had just witnessed.

The vote was carried by acclamation.

Mr. F. YORK exhibited and explained a camera he just had constructed, the principal feature of which was that, although it was oblong in shape, pictures either vertical or horizontal could be taken at will without removing it from the stand. This is accomplished in a very simple manner. The back portion of the camera which carries the slide can be easily detached from the base-board and replaced either horizontally or vertically. To enable this to be done the bellows, instead of being attached as usual direct to the front of the camera, is fixed to a disc of metal fitted to the front in such a manner that it can be rotated a quarter of a revolution. The simplicity and utility of the contrivance excited considerable admiration. He (Mr. York) mentioned that although this form of camera was, he believed, a novelty in this country, it had been in use for a considerable time in France.

A subject, taken from the question box, "Does the burnishing of prints produce any chemical change in them?" was then discussed.

Mr. HARRISON said that, as prints subjected to heat became of a warmer tone, some chemical change might possibly be produced by hot burnishing.

Mr. E. DUNMORE remarked that if any hyposulphite of soda, from imperfect washing, remained in the print it would be decomposed if exposed to a strong heat, as in burnishing.

The discussion—in which Messrs. Ayres, Ashman, Foxlee, and others took part—then became of a desultory character, and no very definite conclusion was arrived at.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting of this Society, held on the 3rd instant, the chair was occupied by Mr. W. Coles.

Mr. J. B. B. WELLINGTON said that he had tried the formula for emulsion given by Mr. Henderson at the preceding meeting. He had attempted to reduce the quantity of water, but found that that gave a coarse precipitate which would not properly emulsify. He succeeded best when adding two or three grains of gelatine after the acetate was formed and before adding the bromide. The silver then emulsified properly, and he produced a transparency printed on a plate made from this batch, but he had not time yet to form a decided opinion as to the rapidity of the emulsion.

Mr. A. L. HENDERSON said that he could, by the method described, get an emulsion without any cooking that would give 25 on the sensitometer. He thought it important that the acetate of ammonia should be neutral. It was not so good either if the ammonia were in excess.

Mr. WELLINGTON thought that he had some excess of acid.

Mr. HENDERSON remarked that in excess of acid some silver was wasted, and the emulsion might be thin.

Mr. A. HADDON said that liquid ammonia was preferable to the carbonate for making a neutral acetate, as the carbonic acid given off from carbonate of ammonia masked the indication of the test paper, and, observing that the undeveloped plate shown by Mr. Wellington was of a rich orange red, inquired whether with that colour the emulsion was rapid.

Mr. HENDERSON replied that, considering the colour, emulsions prepared in this manner were wonderfully rapid. A little acetic acid might be added before coating; this made the blacks very clear.

Mr. W. E. DEBENHAM said that colour was no certain guide to the rapidity of emulsions. In some cases the colour of an emulsion had been referred to as evidence of its speed. Some orange or even red plates were quicker than some blue ones.

Mr. A. COWAN had just been asked to try the speed of certain plates; one of these was red and was slightly quicker than the other—a blue one.

The CHAIRMAN thought that colour was a guide in any particular process, but not when comparing the plates made by one method with those produced by another plan.

Mr. HADDON inquired whether Mr. Cowan found the orange or the grey emulsion gave the more density.

In the particular plates to which reference had been made Mr. COWAN had found a little more density with the grey.

Mr. HENDERSON thought that acetate of silver washed and added to bromised collodion should make a good emulsion.

An exposure shutter lent by Mr. Turnbull, of Edinburgh, was handed round amongst the members.

Mr. WELLINGTON then gave the following formula for an emulsion:—

Nitrate of silver	50 grains.
Citric acid	50 ,,
Water	4 ounces.

To this sufficient liquid ammonia (about one and a-half drachm) to redissolve the precipitated silver was added, and the solution was then to be stirred into the following:—

Bromide of potassium	45 grains.
Iodide ,,	1 grain.
Carbonate of ammonia	30 grains.
Gelatine	10 ,,
Water	4 ounces.

Mix all cold. The colour at first was ruby, but after twelve hours it became blue, and two hundred grains of gelatine previously soaked was added, and, after melting together and setting, washed in the usual way. He had tried a similar mixture, but with the application of heat at 150°—instead of the addition of ammonia to obtain rapidity—it became blue and very thin.

Mr. HENDERSON related some experiments with artificial illumination for the dark room. He had used the light reflected from a phosphorescent tablet without any transmitting medium. He thought that the tablet at first absorbed the actinic rays and so prevented them from acting upon the sensitive plate, but that the tablet soon became saturated, then gave off actinic rays, and acted like an ordinary reflector. It was necessary, therefore, to change the tablet frequently. To avoid this he had adopted another plan. He had used two phosphorescent tablets as transmitting screens. The first one, he considered, absorbed the photographic rays, and let those only pass through the second which it was safe to use.

Mr. DEBENHAM thought that in the first case mentioned the phosphorescent reflector was, at starting, in the same condition as an ordinary reflector, but afterwards gave out rays of photographic power, and was worse than the ordinary reflector. As to using phosphorescent paint to transmit light through: it was not probable that it would give any safer light than another medium of similar colour and opacity.

Mr. COWAN said that he had added ammonia to finished emulsion, as had been recommended. He had put in five minims to the ounce. At first there seemed to be no difference in the plates coated with it, but after keeping a few days the ammonia plates gave in parts no image at all.

The second Thursday this month falling upon the eve of Good Friday, Mr. Debenham's lecturette, *On Lenses*, will be given on the 17th instant, instead of the 10th, as previously announced.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held at the Manchester Technical Schools, on March 13th,—the President, Mr. John Pollitt, in the chair.

The minutes of the previous meeting were read and confirmed. The ballot was then taken, and the following gentlemen were admitted members:—Messrs. W. Jenkinson, J. T. Lees, Levi Lambert, H. Pope, and Charles Coote.

Mr. Jos. GREATOREX read an interesting and somewhat amusing paper, the subject being *A Summer Holiday*, consisting of notes of a recent tour in Switzerland. [See page 218.]

Mr. S. D. MCKELLEN gave a practical demonstration of the printing on argentic-bromide paper as manufactured by Messrs. Goodall and Steven, and also made an enlargement on the same paper, about 12 × 10, from a 3 × 4 negative. The method of enlarging adopted by Mr. McKellen was to illuminate the negative by the aid of a sciopticon lantern, and he stated that he had found a sheet of ground glass interposed between the negative and condenser a great improvement.

The HONORARY SECRETARY said if the condenser was large enough to cover the negative the ground glass was unnecessary.

Several prints and enlargements were exhibited by the demonstrator, and admired for their pure whites and general brilliancy.

Votes of thanks were passed to Mr. Greatorex and Mr. McKellen.

The CHAIRMAN then referred to the interesting paper read at the previous meeting by Mr. Rishton, and said that but for the lateness of the hour he should have invited a discussion on swing-backs and swing-fronts, as he knew there were several members who had studied the subject and had decided to communicate their views. He would, therefore, have great pleasure in bringing the matter forward at the next meeting.

The HONORARY SECRETARY said he should give them a communication and probably a demonstration in making enlargements from small negatives at an early date.

An interesting and enjoyable evening terminated at a late hour.

NORTH STAFFORDSHIRE PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting was held on Wednesday evening, the 2nd instant, at the Mechanics' Institute, Hanley,—Mr. R. S. Burgess occupying the chair.

Mr. W. F. Fishburn was elected a member of the Society.

The HON. SECRETARY exhibited a half-plate tourist apparatus by Mr. C. E. Elliott, of London. The elegant appearance and finish of the camera were much admired, the excellence of the dark slides being also remarked upon.

A paper upon and demonstration of the process of *Photomicrography for Beginners* [see page 234] having been given by Mr. W. B. Allison, a vote of thanks was unanimously passed to that gentleman; and, after some interesting conversation upon the subject of photomicrography, and Mr. Allison had passed round some transparencies upon collodio-bromide, the meeting terminated.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of this Society was held in Lamb's Hotel, on Thursday, the 3rd instant, at which there was a good attendance,—Mr. W. D. Valentine, Vice-President, in the chair.

The CHAIRMAN read a letter from Mr. J. C. Cox expressing his regret at not being able to be present, and thanking the members for their kindness in re-electing him President. He (the Chairman) said the Society was fortunate in possessing in their President a gentleman who was an enthusiastic photographer, an acknowledged artist, and of good social position. Mr. Cox had spared neither time nor money in promoting the welfare of the Society ever since its establishment, his latest gift to the Society being a fully-equipped developing room, which was already being largely taken advantage of.

The following new members were admitted:—Messrs. W. W. Moncrieff, D. R. Mitchell, John Jones, and D. R. Malcolm.

The election of office-bearers was then proceeded with, and the following is the list for 1884-85:—*President:* Mr. J. C. Cox.—*Vice-Presidents:* Messrs. W. D. Valentine and D. Ireland.—*Council:* Messrs. G. D. Macdougald, J. Geddes (Arbroath), H. G. Fraser, A. C. Lamb, Alfred Guthrie, and G. F. Rodger.—*Hon. Treasurer:* Mr. John Robertson.—*Hon. Secretary:* Mr. D. Ireland, Jun.—*Auditors:* Messrs. John Mess and John R. Wilson.

A special vote of thanks was awarded to the Hon. Secretary and Hon. Treasurer for the efficient manner in which they had fulfilled their duties in the past session.

Mr. G. D. Macdougald then read an able paper on *Development*, and gave the particulars of a new developer which yielded negatives of a peculiarly rich, non-actinic colour, another advantage being that all the ingredients were dry, only requiring the addition of water to form the developer.

Some discussion took place as to whether the negative was better to be of a blue or of a non-actinic colour. The opinion of the meeting was that the latter was preferable.

Dr. J. K. Tulloch said that a gelatine negative rarely printed quite satisfactorily without after-treatment, and that he was in the habit of applying bichloride of mercury, followed by ammonia, to nearly all his negatives. This treatment seemed to bring up the detail in the shadows, while the high lights, being already opaque, were not affected by it.

The Chairman was greatly averse to the use of mercury, as he found that negatives thus treated faded in the course of a year or two. On his motion a vote of thanks was awarded to Mr. Macdougald. He (the Chairman) also showed a negative in which the sunlight on the pillars and wall of the interior of a cathedral was perfectly clear glass, the reversal being caused by over-exposure.

A vote of thanks to the Chairman closed the proceedings.

Results of competition for February:—*Portrait Taken in Room:* J. Sturrock, 200 marks; Dr. Tulloch, 150. For March competition, *Still Life*, there was only one entry, Mr. D. Ireland, Jun., 200 marks.

Correspondence.

April Meeting of the Photographic Society of France.—Retouching Pencils.—Gelatino-Bromide Films.—A Demonstration by M. Audra for the 25th instant.—Mr. Henderson Invited by the Photographic Society of France.—On Exposing Films.—A New Dark Slide.—M. Mauduit's Electric Movement for Instantaneous Shutters.—A New Seeker.—Ceramic Photography.

The April meeting of the Photographic Society of France was held on Friday last, the 2nd instant,—M. Davanne in the chair.

M. Gilbert, a French manufacturer of blacklead pencils, presented a series of pencils for retouching photographic negatives. Several members spoke highly in their praise. Patriotic feelings were then aroused, as we have been tributary for years to a Prussian house for this very useful article. A discussion took place upon the best means of rendering the hard, and sometimes very brilliant, surface of the gelatine negative sufficiently soft to retouch upon. Emery powder and many other "dodges" were proposed. The most interesting to notice was to pour spirits of turpentine over the surface of the negative. Another method was to plunge the negative for an instant into a five-per-cent. solution of acetic acid.

M. Bornstein presented some gelatino-bromide films, which he requested to be experimented upon. No specimens were shown.

M. Audra offered to give a private *soirée* on the 25th inst., at which he would publicly demonstrate his method of making emulsions. The Society accepted with pleasure and due acknowledgment this innovation, and offered their place of meeting to M. Audra for his demonstration.

This idea does great credit to M. Audra, and is a novelty. In England these public demonstrations are common, but here they are unknown.

I had the honour of informing the Society that Mr. A. L. Henderson had succeeded in making a gelatino-bromide of silver emulsion by precipitating the silver from aqueous solutions, and then adding the necessary quantity of gelatine. Moreover, Mr. Henderson had invented a new coating apparatus so simple in its construction that the clean glass is put into one end, a tramway seizes it, carries it under the coating machine, and then stacks the plates ready for the drying cupboard. Mr. Henderson proposed to visit Paris in order to exhibit practically the results of these new ideas to the Photographic Society of France.

The Society passed a vote of thanks to Mr. Henderson, and begged me to inform him that they would be most happy to welcome him among them.

MM. Bayard and Trevaux presented a means of fixing films in the camera. As their system is identical with that of M. Leon Vidal I will not repeat it, as I gave a full description in a former letter. Diachylon is employed to hold the film upon an opaque surface of zinc or ebonite. This manner of holding the film has been found to be far superior to that of placing it under a glass plate during exposure. The light impinges directly upon it instead of first going through a sheet of glass. The refraction of the glass, not to speak of absorption, is sufficient to prevent its employment.

M. Mackenstein presented a very novel double dark slide. The shutter is made with very narrow bands of wood glued upon a piece of linen, and is very flexible. Although the slide is double, only one shutter is required for the two. The frame, when in its place upon the camera, can easily be opened by pulling up the flexible shutter. In so doing the sensitised glass plate is uncovered. When the exposure is terminated the flexible shutter is put into its place, the dark slide is turned, the other end of the flexible shutter is pulled out, and the second plate is exposed. Having only one shutter for the two sides of the dark slide, the latter can be made very thin and having a minimum of weight.

M. Mauduit presented another instantaneous ratchet or catch for rapid shutters. Instead of a pneumatic ball and tube he employs an electric current, which, he says, has the advantage of not imparting motion to the camera.

M. l'Abbe Fernique presented a little instrument which he had invented in order to see the exact position of a moving object in taking instantaneous pictures. It consists of a kind of lens which is fixed upon the top of the camera. The operator can see the image he wishes to reproduce reflected upon the instrument. He can then choose the proper moment to take the picture.

Ceramic photography is getting into fashion. Since Mr. Henderson's public demonstration of his excellent process hundreds have been experimenting in order to obtain the *ne plus ultra* of photographic productions—that is to say, the brilliant and permanent enamel. The dusting-on process and the substitution process of our indefatigable friend Mr. Henderson have been brought before the readers of The British Journal of Photography; each has its respective merits and its inherent faults. A gentleman of St. Petersburg has found a method of obtaining photographs on chinaware or enamels by employing the carbon process. Instead of the ordinary colour employed he macerates with gum, honey, and metallic oxides. This emulsion is spread upon paper, sensitised by a bichromate of potash solution, and treated in every way like an ordinary carbon print. The image is then transferred to glass, enamel, or chinaware to be burnt in. The great superiority of this process over all others consists in the advantage it gives the operator in getting the depth of colour he desires, and also in the simplicity of the manipulations. Ere long we may expect to obtain permanent burnt-in proofs as easily and as cheaply as the well-known *carte de visite*.

E. Stebbing, *Prof.*

25, *Rue des Apennins, Paris, April* 7, 1884.

CANARY MEDIUM.

To the Editors.

Gentlemen,—With your permission I should like to say a few words upon the last paragraph of Mr. G. Smith's contribution in your issue of the 28th ult., and to shew why it is that canary medium has been used in the north of England.

At a meeting of the West Riding of Yorkshire Photographic Society it had been arranged to spend an evening in the development, &c., of gelatine plates, and a member had promised to provide a suitable lantern, which proved to be of the kind usually considered essential—that is, a deep ruby glass, a candle being the source of light. With that arrangement any object more than about a foot from the lantern was in darkness, and developers, &c., had to be found by touch rather than sight.

Mr. Bridges, of Bradford, also brought a lantern, and after the necessary communication had been made to the gas bracket it was lighted. It was now possible to see the features of each other, even when some sixteen or twenty feet away from the light, the whole room being filled with what looked almost to be white light after the experience of the ruby. I believe there was not a single member present who had not grave doubts as to the possibility of such a light having any practical value. I can truly say that I was a sceptic.

I had two negatives with me which experience had proved to be veritable twins. After dividing a gelatine plate in two, exposing the halves to the ruby and canary lights respectively, and developing together close to the glasses of the two lanterns for ten minutes, in the same solution, we succeeded in getting a faint transparency on each. Opinions differed as to which was the more exposed; the impression was so very slight that a comparison of details was impossible. With such a result no member could believe that either lamp arrested all the actinic rays.

One broad fact was made evident—that whereas you were compelled to be close to the ruby light, and had to make a prolonged inspection to find out the progress of development, with the canary you might be much further away, and a momentary glance would reveal progress.

The opponents of canary have usually made one great mistake in comparing chemical illumination, and not noticing visual illumination, as an illustration. I might instance an experiment made, I believe, by Mr. Cussons, of Southport, who put in a frame a ruby glass and a piece of canary medium side by side, put a plate behind, exposed, and developed, Two substances might be tested in such a way and yield identical results; yet in one case the ratio of actinism to visibility might be as five to one hundred, and, in the other case, as five to ten. If two rooms were lighted through such media until objects were equally visible to the eye, there would be ten times as much fogging power in one room as in the other.

And here I have a word of fault to find with the Editors. A letter I sent pointing out the relation of these items of chemical and visual power was "boiled down" into an intimation in "Answers to Correspondents," stating a fact without a particle of evidence to support it. What is the practical good in using canary medium? I venture to say that if you go the round of those studios where it is used you will not find that abnormal shortening of the focus of the eyes which is said to be found where ruby-lighted dark rooms are employed.

I have used ruby and had great pain in my eyes, which left me shortly after I put away the ruby and substituted canary, and I beg to thank Mr. Bridges for the share he had in preserving my eyesight.

It is too late to judge canary solely upon theoretical grounds. Two or three years' practical experience affords data which ought to play a part in estimating its value.

"Northerners must have been working slower plates." As northerners and southerners were alike in an experimental stage, and had not settled down to the exclusive use of the plates of some favourite maker, it is evident that the plates developed under a canary light were, in many cases, of southern production, and, in fact, identical in character with those used by the people who rejected canary medium.

If agreeable to the Editors, and thought likely to be of interest, I could send a description of my dark-room window, which allows a considerable amount of modification of lighting under ready control.

I notice an inquiry has been made about soda instead of ammonia in alkaline development. If ammonia produce chronic bronchitis, and the substitution of soda or potash could be effected without introducing some other drawback, the value of such a change would be health and life to the operator.—I am, yours, &c., JOHN GARRATT.

Dewsbury, April 2, 1884.

P.S.—Since writing the above I have been trying potash as a substitute for ammonia, and send you two plates. No. 1 was developed with carbonate of potash twenty grains, water one ounce, and bromide of potassium half-a-grain. No. 2 with carbonate of potash twenty grains, soda sulphite twenty grains, bromide of potassium half-a-grain—in each case with an equal amount of pyro. solution six grains to the ounce. The soda sulphite is added to potash carbonate, no neutralisation with citric acid, and the effect is most marked in improving quality. A portrait I have since taken is singularly rich in delicate tones.—J. G.

ACCIDENTS AT RECENT LANTERN EXHIBITIONS.—A SUGGESTION.

To the EDITORS.

GENTLEMEN,—I should be very glad to hear that some photographic society had taken this matter up and offered a prize for the best safety tube and the best back-pressure valve. Although I have but little time at my disposal, I would willingly assist in testing these tubes and making the award. T. FREDERICK HARDWICH.

Shotton Vicarage, Castle Eden, April 7, 1884.

A QUESTION OF PRIORITY.

To the EDITORS.

GENTLEMEN,—In my paper, referred to by Mr. Collier, I find I have been scarcely explicit enough. The action of a solarised bichromated film imprinting its image on another bichromated film was brought out as a process by M. Marion, of Paris, under the name of "Mariotype," a full account of which is to be found in the *Journal of the Photographic Society* for May, 1873.

Captain Abney's researches on the continuing action of light on bichromated films had been made prior to this, and Mariotype was more or less a practical outcome of these researches.—I am, yours, &c.,

Cross Park, Partick, N.B., April 4, 1884. WILLIAM LANG, JUN.

[The original paper by M. Marion, of Paris, together with leading and other articles on the subjects therein brought forward by that gentleman (since deceased) will be found in the issues of May 16th and 23rd of THE BRITISH JOURNAL OF PHOTOGRAPHY for 1873.—EDS.]

UNIVERSAL ATTRACTION AND ITS RELATION TO THE CHEMICAL ELEMENTS.

To the EDITORS.

GENTLEMEN,—Since your remarks, last week, upon my recent publication, contain certain statements which require alteration to agree with facts, I request you will rectify same in your next issue, though I quite believe they may have originated in want of clearness of expression on my part rather than in want of acquaintance with recent discoveries or want of accuracy on yours.

I am made to speak of Nature choosing *figures* when speaking of the chemical atoms and their numerical equivalents. What I said was that "it is a libel upon Nature to say she made such *condensed masses*," as the chemical atoms are made to appear to fit the Newtonian philosophy. I am represented as confessing want of success in search of *definitions* of "mass" and "weight." What I sought unsuccessfully were *values* for these in the Newtonian equations consistent with the facts of chemistry. My "terrestrial spectrum" illustration is open to grave misconception, separated as it is from its contiguous paragraphs.

Leaving now the facts, and coming to questions of opinion, I seek in no way to question yours or others, but I tender you my thanks for the courtesy and tolerance which has prompted you to notice in a journal devoted to the light science a subject destined to throw considerable light into a dark corner of the basement premises which underlie all science. Your courage in noticing, even as you have done, a subject which involves an inconvenient dilemma that some have not been slow to appreciate in a manner less scientific than significant entitles you to the thanks of every lover of fair and free inquiry.—I am, yours, &c., W. B. SHARP.

Edinburgh, April 5, 1884.

GLOY.

To the EDITORS.

GENTLEMEN,—In a recent number of THE BRITISH JOURNAL OF PHOTOGRAPHY there is a damaging paragraph about gloy, as it is not only not made from dextrine, but in any one of our products there is not a particle of dextrine. Moreover, we are told that our gloy No. 2 mounts photographs better and cheaper than any other adhesive. Samples have been frequently submitted to us; and, in fact, our attention has been called to your remarks by a photographer who constantly uses it.

You must have made experiments with some quality of gloy not intended for the purpose, and we will thank you to insert this letter in your next issue, and call attention to the subject.—We are, yours, &c.,

St. Mary's-chambers, St. Mary Axe, April 4, 1884. GLOY MANUFACTURING CO.,

[The above communication reached us too late for insertion in our last issue. We can find no reference whatever to dextrine in connection with "gloy" in any of our recent numbers, and think it rather unnecessary on the part of the Gloy Company to exercise so much energy in repudiating a harmless ingredient which they have *not* been charged with using, while they calmly ignore the more dangerous substances which our short paragraph mentioned as appertaining to the preparation of their adhesive. If the Company can with equal frankness—and we may add truth—assure photographers that not only dextrine, but also caustic alkalis and strong mineral acids, find no place in any one of their products—that, in fact, our paragraph is incorrect—we shall be glad, and photographers may then be able to use gloy with comfort.—EDS.]

Notes and Queries.

"As regards the 'ownership of negatives,' discussed in the last number of your Journal, an analogous case occurs to me. You go to an engraver and order visiting cards, he prepares a copperplate (or negative), which becomes your property on payment.—G. H."——Nay! Not so! The engraver advertises "your name-plate engraved *and* fifty cards for half-a-crown;" whereas the photographer does not stipulate to give up the negative.

"GENTLEMEN,—You are quite right in your reply to 'A. H. B.' in last Journal. Protosulphate of iron is utterly untrustworthy as a developer for dry plates—at anyrate for those formed of collodio-bromide. Let me here take advantage of the *Notes and Queries* to ask whether any one has made systematic experiments with ferrous oxalate in connection with dry collodion, and if it possess that enhanced rapidity once hinted at by Mr. W. Brooks.—S. S. A. B."

F. DUGON, replying to the remarks of J. Berryman, which appeared in our *Notes and Queries* last week, and in which he stated that he had been ungenerously misled by others, says:—"I have witnessed a free demonstration of an enamel process, and have succeeded fairly well in my very first attempt. The innuendoes thrown out by your correspondent seem to be somewhat unjustifiable, and I write this in the interests of those gentlemen who have written on the subject."

J. W. G. says:—"Will you answer me the following questions? 1. How to form an idea of the focus of a lens minus a camera.—2. The best all-round colour for an outdoor background.—3. The best lubricant for prints previous to burnishing, and how to use it."——In reply: 1. Hold the lens close to a white wall at the back of a room, and move it slowly out until an inverted image of those objects outside which are situated at a distance is seen to be as sharp as possible; then measure the distance between the optical centre of the lens and the wall, and the result will be a tolerably near approximation to the equivalent focus.—2. This is purely a matter of taste. Some prefer drab, others lighter, and others still darker tints.—3. Like the previous question there is no "best" in this matter, as there are many opinions. Try a two-grain solution of wax in ether. For the manner of using a burnisher see any manual of instructions.

"IN reply to the query of Geo. Thompson respecting a hygrometer in which the indications of moisture are made by the rising and falling of a column of mercury, I beg to say that if he will fit a glass tube (the bore of which is large enough to allow a pin to drop through it) to a bulb composed of animal membrane and filled with mercury, the bulb will contract and expand according to the state of the atmosphere as regards moisture. The bladder of a rat has been recommended in some old treatises on Natural Philosophy as the best membraneous substance for a bulb. I once constructed a hygrometer of this class, and although the mercury rose and fell I regarded it rather as a toy than a proper philosophical instrument, and never put myself to the trouble of graduating the scale. I do not see how it is possible that any real accuracy can be obtained by its indications, as there is the thermometric change in the volume of the mercury to note as well as the rise that takes place by the construction of the bulb.—AULD REEKIE."

"I AM building a studio in which I require to get light from the south side. I propose to make the roof clear glass and the side ground glass. The roof, I presume, will be safe from interference by my adjoining neighbour on account of its not overlooking his premises? Will not the upright light at the side be equally beyond his power to prevent, as the window, being non-transparent, will not overlook him either? I do not know if this point has ever arisen in a court of law.—BROMO."——So far as we remember this is a point in lighting that has not previously been raised, and we shall be glad to see it discussed.

W. C. C. says:—"Would you kindly inform me what is the best method by which I can get a 'tooth' to the gelatine film for retouching upon? I have tried several ways, but have not succeeded in getting it to my satisfaction. I have used various media, but, instead of producing a 'tooth' to the surface, they have been of such a greasy character that the pencil will not bite. I have been using Wolff's three and four H leads, and have tried both with varnish and without. Would you inform me how I can tone the ready-sensitised paper quicker? I have only lately taken to use it, and find it takes a surprising time to tone. I have tried ammonia to neutralise the acid in the paper, but without any mere success."——Instead of replying to these queries we submit them to our correspondents, as being suggestive.

"I SHOULD be much obliged if you could tell me in your next number how to prevent halation caused by a window directly facing the camera in photographing an interior.—L. W. J."——In reply: The best way to prevent halation under the circumstances described is to apply to the back of the plate a mixture of any colouring matter of the nature of Venetian red or Spanish brown, with water, glycerine, and gum arabic. The proportions of these should be such as to form a solid coating capable of being removed by rubbing with a wet sponge. By this coating the light which would be reflected from the back of the plate on to the sensitive surface is absorbed. An application of wet, red blotting-paper to the back would answer the same purpose; but it is imperative that it be wet, and in optical contact with the glass during the exposure.

"ON page 92 of the ALMANAC for 1884, among jottings (No. 13 in order from beginning), occurs the following:—'Shreds of gutta-percha dissolved in benzole,' &c., &c. Would you kindly answer me a query in your next issue as to how to dissolve these shreds? I have had some soaking in benzole for three weeks, and they are not touched in the slightest degree by the solution.—H. ASH."——In reply: It is probable that the refractory gutta-percha will succumb to the influences of a tolerably warm sand-bath. The jotting in question is one of a number of useful selections made from this Journal by the Rev. Locke Macdona, B.A., from whom we shall be glad to receive an answer in this matter. We have frequently dissolved gutta-percha in rather common naphtha, and we do not see how it resists the more potent solvent powers of benzole. We need scarcely say that, when heat has to be applied to such inflammable materials, caution must be observed.

Exchange Column.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHS REGISTERED.—

Edwin Debenham, 79, Princes-street, Edinburgh.—*Four Photographs of the Clergy of St. Mary's Cathedral, Edinburgh.*

William Duncan, Clifton Vale-terrace, Clifton Junction, near Manchester.—*Photograph of Brackley Old Unitarian Chapel.*

Squire Knott, Yorkshire-street, Oldham.—*Photograph of Mr. Ben. Brierley.*

Joseph Barwise, 22, Station-road, Workington. — *Photograph of St. Michael's Church.*

☞ Several "Exchanges" are unavoidably left over till next week.

H. HAWKINS.—After the remedies you have tried we should advise you to procure a fresh sample of paper.

CHROME ALUM.—It is not advisable to use the bath after it has become discoloured. The solution is not costly.

F. A. M.—The effect is very curious. Probably it is caused by particles of dust settling on the films whilst they are drying.

EDWIN GRANT.—From two to three guineas and travelling expenses will be a fair charge; that is, if your work be of first-rate quality.

VIOTTI KROMMER.—The water becoming "milky" will do no harm, nor prevent the pictures from toning. All waters, as a rule, except distilled or rain water, produce turbidity with silver nitrate.

A. G. (Printer).—Without making an analysis it would be impossible to express an opinion. Bristol board would, no doubt, be perfectly safe if of good quality. Yes, copying a copyright picture at all is an infringement of the law.

WARWICK.—We fear you will have to be content with warm tones with the sample of paper you are using. From the examples forwarded it is clear that purple tones cannot be produced with it, and the attempt to obtain them would only end in mealiness.

J. P. B. (SPOT.)—If cyanide of potassium will not remove the spots we fear nothing else will be effectual. In future we should advise you to protect the film with varnish, and also bestow more care upon the removal of the last traces of the hyposulphite of soda.

PUZZLED PRINTER.—The marks across the prints are caused by the "cotton cord" upon which you have hung them to dry. Probably it contains some traces of chlorine with which the fibre was bleached. We had a similar experience ourselves some few years back.

A. G. GRIGSTONE.—The defects are more imaginary than real. Try the instrument, and you will doubtless find in practice that its working qualities are very little, if at all, impaired. However, be that as it may, then, there is no remedy but to have new glasses.

S. J. G.—The chalkiness in the carbon prints is due to the tissue being in a too-soluble condition. The remedy is to keep the tissue longer between sensitising and printing. Another remedy is to sensitise on a stronger bath. We are assuming that you are not employing the water too hot in the development.

THOS. BILLINTON.—We are unable to say if there be a good opening for a photographer in the town mentioned. This we do know, however, there are some excellent photographers there, and unless you can surpass them we think you stand a somewhat poor chance of success in commencing a new business. The town is by no means a large one, and, as we have said, already possesses several good photographers.

J. T. HOULSTON.—The design for studio marked "No. 3" is certainly to be preferred to either of the others. If you have space it will be advisable to build it five or six feet longer than the plan shows, as this will enable you to take groups with greater convenience, and from your note we imagine this is a consideration with you. With regard to the side light: it will be better to stop off rather less at the background end—say four feet, instead of six.

A COUNTRY ARTIST.—The sand-blast process is largely employed in producing the grained surface on opal glass. It possesses some advantage, inasmuch as it is less liable to scratches. These are frequently very prevalent in hand ground glass. The objection to sand-blasting is that if there are any minute air-bells in the glass near the surface they become broken and form small holes. Opal glass with the sand-blast grain is less costly than that in which the grain is produced by hand grinding.

*** Owing to our going to press a day earlier than usual this week several communications which arrived late must stand over till our next issue.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 16th inst., the subject for discussion will be—*On Packing and Repacking Dry Plates when on a Tour.* For Monday next, the 14th instant (bank holiday) an outdoor meeting has been decided upon; but, owing to the earlier publication of this Journal, the locality selected on the 9th instant will have been chosen too late for insertion. Members and friends desirous of joining may ascertain particulars by application to the Honorary Secretary.

A FRAUDULENT PHOTOGRAPHER.— At the Leicestershire Quarter Sessions, on Tuesday last, the 8th inst., George Daniels, a photographer, of Nottingham, was indicted for having, on the 15th of August and 25th of December last respectively, obtained money under false pretences from Fanny Upton and Thomas Davies. In addition to this charge (particulars of which appeared in our issue of February 15th, page 111), the prisoner was further indicted with having stolen a lens, worth £5, the property of Professor Colton, of Ratcliffe College, on the 24th of November last. The evidence for the prosecution in the latter case was to the effect that on the day in question the prisoner called at Ratcliffe College and requested Professor Colton to allow him to take a photograph of several of the pupils. Professor Colton, who practises photography himself, placed his dark room at the disposal of the accused. The prisoner, after some three hours' interval, left the room, which was then locked up by its owner. When Professor Colton again visited his dark room, in March last, he found that one of the lenses in the triplet lens attached to his photographic apparatus was missing, and another glass put in its place. The lens, which was produced in court and identified by the owner, was valued at £5. Mr. Toller for the defence argued that, owing to the great resemblance between the lenses, it was quite probable that the accused, when leaving the dark room, appropriated the wrong lens in mistake. The jury found the prisoner guilty on both counts, and he was sentenced to six months' imprisonment with hard labour.

JOURNAL OF PHOTOGRAPHY.

No. 1250. Vol. XXXI.—APRIL 18, 1884.

ADAPTING THE CAMERA TO LANTERN PURPOSES.

The rapidly-increasing popularity of the optical lantern leads necessarily to a growing demand for fresh slides, and, as the large army of amateur photographers attach a greater value to the pictures of their own production than to those of others, we may anticipate a considerable activity on their part during the approaching season in this particular branch of negative production.

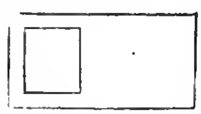
The negatives suitable for the purpose may be divided into two principal classes—those which require subsequent reduction, and those which, being taken on quarter-plates, are suitable for contact printing. But objections may be, and are, raised against both these classes. In the first place, the lantern picture is, as a rule, when not circular, square, or nearly so, while the sizes of none of the plates in general use approach very closely to that shape. Plates of such sizes as 5 × 4, 10 × 8, or, better still, 12 × 10 are near enough to the regular shape to answer most purposes; but, even with these, it is frequently found that some portion of the subject must be left out of the "slide" and thus spoil the composition.

The tendency in focussing and arranging the composition of a landscape is to make the best of the material before one on the size of plate represented by the focussing glass, and in the case especially of a large plate it would be obviously unwise to make the original negative subservient to the requirements of the small lantern picture. Hence, on looking over a collection of such negatives, it is often surprising how few of them lend themselves readily for reduction to the dimensions and shape of the lantern slide without in some degree spoiling the composition.

If, however, we turn to the far more popular sizes—such as $7\frac{1}{2} \times 5$, $7\frac{1}{4} \times 4\frac{1}{2}$, or half-plate—we find these difficulties to be even greater in consequence of the wider disproportion between the length and height of the picture. The obvious reply to these objections will be that it is easy to provide a special camera of quarter-plate size, and to take negatives directly suitable for contact-printing, and including just so much of the subject as may be desired for the purpose of the lantern picture. But a great many outdoor workers will object equally to going out with "only a quarter-plate camera," and to carrying two instruments. This forms the objection in the second case, and though it is true the quarter-plates may be used for the production of enlargements the objection is, we have reason to know, a valid one.

We propose, therefore, to describe here a slight adaptation we have had made in one of our own cameras which renders it available both for lantern and ordinary purposes at will, and which involves no expense beyond a few pence, and practically no increase of *impedimenta*. The camera in question is of the popular size, $7\frac{1}{2} \times 5$, but the arrangement is equally adapted to other similar sizes.

The first necessity is to cut, in the inner framework of the camera to which the bellows are attached and immediately in front of the focussing glass, a sunk rebate of the same size as, and corresponding with, the position of the plate when in the dark slide. The depth of the rebate need not be greater than one-sixteenth of an inch, or just sufficient to take a sheet of zinc or stout cardboard. The latter forms a mask by which one-half of the plate is covered during the exposure of the other half, and two pictures can be produced on the one plate. This purpose is effected by cutting an aperture of the desired size and shape in the centre of one-half of the zinc plate, thus:—



This plan is better than employing the central partition usually supplied with cameras of the sizes we have named, since it takes less time to place the mask in position or remove it. It allows lenses of any focus up to the full length of the camera to be used, whereas the central division being intended for stereo. purposes is rarely longer than 6 inches; and last, but not least, if the aperture be of the dimensions of 3×3, the operator sees at the time of focussing exactly the amount of subject he will have on his slide, and runs no risk of spoiling the composition by crowding in too much.

Except with a lens of very short focus there is no absolute necessity to shift it from the centre of the camera front. If it be capable of covering the whole of the plate when in that position it will, of course, cover the half; but where it is possible, by lengthening the slot in the horizontal sliding front, to bring the lens opposite the centre of the half-plate, or nearly so, it is obvious the best portion of the lens will be utilised.

After taking one picture the mask is merely reversed, the front, if movable, pushed to the opposite end of the slot, and the next picture taken. Or if a whole plate be required the mask is removed altogether.

With regard to the advisability of developing two different exposures on the same plate, we may say that we prefer to cut the plates previous to development, and thus develope each exposure separately.

ON PHOTOGRAPHING SILVER PLATE, &c.

It is no unusual circumstance for photographers to be called upon to photograph silver or gold plate, jewellery, and other *objets de luxe* of a similar character. Indeed, many gold and silversmiths, now-a-days, after they have completed a communion, dinner, or tea service of exceptional design, make it a rule to have it photographed prior to delivering it to the customer. Jewellers, too, often take advantage of photography to portray their handicraft, when it happens to be of an unique or special design. It is likewise becoming very customary, when a testimonial is presented, to have it photographed, and for a copy to be supplied to each subscriber. Wedding-presents also are frequently required to be photographed; indeed, photographs of the entire collection, in a group, of the wedding-presents received by the happy couple are now becoming very general.

When the pictures are required by the manufacturer for trade purposes the photographing is generally deputed to those who make this class of work a speciality; but when for private purposes the work usually falls to the lot of the portrait artist, who, possibly, has had but little or no experience in this particular direction, and may not even have the best appliances at hand for the purpose. As a consequence, he often fails to secure a picture that proves quite satisfactory, the fault generally being that the high lights of the picture, or the frosted portions, are a chalky, white mass, completely devoid of detail, and the burnished parts black patches, showing nothing but the reflected sash-bars of the studio. To photographers so situated a few practical hints may be an advantage.

Presuming a commission has been received to photograph a service of plate or plated goods, the best result will always be secured if the picture can be taken before the articles are finally polished or burnished. It is at this stage, it may be mentioned, that manufacturers usually have the photographs taken. It sometimes happens, however, even in the unpolished state, that the metal is too brilliant to photograph well, but an oily rag rubbed over its surface will at once enable the difficulty to be overcome. However, it is not with the photographing of the unfinished articles that we at present intend to deal, as these are, by the way, usually entrusted to the hands of experts in this kind of work. It is of the finished goods we propose to treat, as it is these which are the more likely to come into the hands of the portrait artist, and it is he who is most in need of assistance.

The chief difficulty in photographing plate arises from the white or frosted portions impressing the sensitive film before the burnished parts, which in silver, under certain conditions, are practically black. Consequently, when the developer is applied, the bright portions flash out and acquire intensity before the detail in the darker ones can be brought out. But if the burnished portions be dulled, much of the difficulty of obtaining a harmonious picture at once vanishes.

There are several "dodges" resorted to by photographers for this purpose. The best practically, and the one most generally adopted by experts, is dabbing the burnished or excessively-bright parts lightly, but evenly, over with a piece of common glaziers' putty. This produces a dead surface which photographs remarkably well, and enables the most delicate design to be clearly depicted. After the photograph has been secured the putty is easily removed by brushing it over with clean, dry whiting. Instead of using common whiting—which often contains gritty particles liable to scratch the metal—precipitated chalk may be substituted; indeed, it is a good plan to make the putty itself of precipitated chalk to avoid risk of scratches. A little of the chalk mixed with almost any kind of oil will answer the purpose.

Another plan, which is frequently adopted, is to dull the surface with moisture by causing a dew to form upon it in the following manner:—After the light has been arranged, the image focussed, and the plate ready for exposure, a piece of ice is placed inside each vessel. The metal, being a good conductor of heat, soon becomes very cold, and the moisture always present in the atmosphere quickly condenses upon it in the form of dew, and so dulls the surface. Immediately the surface is dulled the exposure must be made, as the condensation continues, and eventually the moisture forms into drops and runs down in "tears." As soon as the exposure has been made the ice should be removed, and the vessel dried. In summer, if the weather be exceptionally dry and this method adopted, it may be necessary to sprinkle the floor of the studio with water, or to spread out some wet cloths in the vicinity of the articles to be photographed, in order to supply the necessary moisture. It is obvious that the ice plan can only be applied to vessels, and not to such things as salvers, candelabra, epergnes, and similar articles.

If either of the "dodges" we have described be resorted to the photographing of plate becomes very much simplified. However, it may be well to mention that gelatine plates are preferable to collodion for the purpose, as with them greater harmony will be secured with far less difficulty. A very full exposure in all cases must be given, and the intensity kept back as much as possible in the development until all the detail in the darker portions are fully out.

In photographing groups of wedding-presents—which may consist of the hundred-and-one heterogeneous things of which such gifts are frequently composed—considerable thought and judgment are required to ensure perfect success. Some of the articles may consist of plate, which require very little exposure; while others are of the darkest and most non-actinic character, and, consequently, necessitate a prolonged exposure in order to obtain anything approaching a satisfactory picture. However, by judiciously arranging the articles themselves much of the difficulty can be overcome. For example: the darkest objects should be so placed that they shall receive the strongest, and the brighter ones the most feeble, light. In many cases one article may be so arranged as to cast a shadow over some smaller one, which would otherwise come out too bright. Much may frequently be done by simply altering the angle at which an object is placed, so that if it be of glass or metal it may reflect the light in a different direction. Matters may sometimes be improved if the light be shaded from some of the articles during part of the exposure by holding a large sheet of cardboard between them and the principal light. A sheet of thin muslin stretched some feet above the group will prevent the reflection of the sash-bars of the studio in the polished articles, which is always so objectionable in a photograph.

Before concluding it may be well to refer to the optical phase of the subject. Throughout this article we have assumed that it is a portrait artist who has to take the picture. Now many artists, who usually confine their practice to portraiture, possess only portrait lenses, and these are about the very worst form of instrument that can possibly be employed for the purpose to which we here draw attention. However, a very suitable lens for the work, if not the best, may be extemporised by removing the back lens of a portrait combination from its mount and screwing the front lens in its place—so that the convex side be next the ground glass of the camera—and then inserting a stop (in the usual slot) with an aperture of one-twenty-fifth or one-thirtieth of the focal length of the lens. The size of plate such a lens will cover sharply to the edges with fairly even illumination will be about two-thirds of its focus.

We advise the use of so small a stop, not because it is necessary to secure good definition, but because it will be found in practice that when very light and very dark objects have to be photographed in juxtaposition, a better result—particularly with collodion plates—will be secured with a small stop and a long exposure than with a large aperture and short exposure, as the violent contrasts will be found more equalised in the picture.

PORTABLE CAMERA ADJUSTMENTS.

There are three separate systems by means of which the expansion and adjustability of the camera bodies are effected, namely, simple sliding, rack and pinion, and screw. Each of these has its peculiar advantage, the first being pre-eminently the best as regards simplicity and rapidity of motion or extension.

To extend the camera from its minimum to its maximum capabilities of expansion is by means of the sliding system of adjustment only the work of a second; whereas by the agency of a screw, even one possessing a quick action, some degree of loss of time and rather irksome manipulation must be experienced. Better in this respect is the rack and pinion, which, if an error be not made on the side of having the teeth too fine, answers every purpose in the most admirable manner, except that of (what may be designated) instantaneous expansion.

It is known to those who have had opportunities of studying the construction of certain portable cameras of American manufacture that in some, and these not the least pretentious, the simple sliding adjustment is adopted, the pinching-screw assuming the form of a small projecting lever, and the screw itself being concealed beneath the body. This pinching-screw has a triple or, at anyrate, a very quick thread, so that about a quarter of a turn suffices either to pinch it effectually or to effect its complete liberation.

The objection which is urged against the sliding system is the difficulty of being able to have recourse to extremely-fine focussing. Its cheapness, and the rapidity of transit of the body along the baseboard, are undoubted; but delicacy in focussing is difficult of attainment, the analogy in this case holding good between the coarse and fine adjustment of a microscope bearing a high power, or of an astronomical telescope.

In certain portrait cameras of the same nationality a compromise has been made between the sliding and the screw modes of adjustment; or, perhaps, it may be more correct to say that advantage has been taken of both united in one—a species of *duo in uno*. In this composite system the sliding is effected as in the old French cameras of a former era, in which a piece of brass projects behind, and through which passes the pinching bolt and nut. But in the American portrait camera of the class to which reference is now being made, the brass travelling piece is not directly attached to the camera body, but only connected with it through the intervention of a quick-acting screw, having in its head a deep groove in which works the end of the brass travelling plate, bent at a right angle. The action is such that, when the coarse adjustment has been made and the focus approximately obtained, the pinching-screw is fastened and the fine adjustment then effected by rotating the head of the screw, which, unable to move backwards or forwards itself, owing to the groove of which we have spoken, causes the body of the camera to move on the base-board.

We have been shown an improvement effected upon this system as applied to the portable camera, no matter whether the camera be of English or American design. In this case, as in that described, the travelling brass piece, to which is affixed the clamping-screw, is not attached to the camera body, but supports a strong pinion, which is geared into a short brass rack, one end of which is fixed to the travelling body of the camera. When the pinching-screw is liberated the action of the body of the camera upon the base-board is that of the ordinary, primitive kind, and admits of the instantaneous sliding action of which we have already spoken, and by means of which an approximately good focus may be quickly made. A touch on the side of the pinching-screw immediately renders the whole rigid and incapable of further adjustment so far as the brass runner is concerned; after which the milled head of the pinion, standing in contiguity to that of the pinching-screw, affords the means of effecting the fine adjustment of the focus by the agency of the rack and pinion.

By the means described the special advantages of both systems of adjustment—that of the simple slide and of the rack and pinion—are secured in a manner at once neat, cheap, and effective.

SHELLAC AND ITS SOLUTION.

Considerable prominence has lately been given in various technical journals to the process discovered by Herr Andes, fully described in these pages a short time ago, for purifying and decolorising the ordinary shellac of commerce. Shellac and copal are two of the most largely-used gums employed in the arts, and if the former, as imported, could only equal copal in colour, or, rather, its absence, the already widespread employment it enjoys would be still further developed. There are, of course, means of decolorising it; but all leave something to be desired, while, at the same time, a number of the published methods are utterly futile. Some of them and methods of dissolving the lac it is our purpose to discuss.

To facilitate the work of those of our readers who care to experiment for themselves, it may be serviceable to describe some of the properties of shellac as already discovered by previous investigations. Our readers are, doubtless, aware of the source from which it is procured. The lac insect deposits its eggs in the twigs and small branches of the Bihar tree, and accompanies them with a peculiar matter which entirely encrusts the twigs—a matter which some observers have stated is neither more nor less than the body of the female insect herself, who, after performing her maternal functions, leaves her bodily frame as food for the future brood, who are thus cannibals from their youth. Be this as it may, the encrusted twigs are collected by natives, and are then known as "stick lac." The encrustations taken off are termed "seed lac," which when melted and squeezed through cloth bags spread on the broad surface of a prepared piece of plantain tree, and then, chipped or flaked off, is known as "shellac"—the form best known to photographers. Many varnish formulæ involve the use of seed lac; but, as will be perceived from our brief description, it cannot possess any advantage over shellac, while it is certainly darker in colour and contains more impurities.

The lac in the "shell" form contains two resins soluble in alcohol, and a wax, but not a third, insoluble resin (laccin) found in seed lac, and, according to Watts, in his *Dictionary*, is soluble in "hydrochloric acid, acetic acid, potash, soda, and borax, but not in ammonia." It is somewhat singular that the latter statement should be made, for a now well-known method of dissolving shellac for certain photographic purposes is entirely based on its solubility in that menstruum or the carbonate, either of which may be made use of, the only secret being that heat is to be employed to aid the dissolution. The method of dissolving in borax has been long known, and indeed we believe it is the one practised by the hatter in producing those wonderful structures with which the average Briton covers his head.

The presence of the borax, however, militates against its employment in photography, and to obtain an aqueous solution of the resin nothing, perhaps, is better than to place it in a water bath at boiling point, cover it with boiling water, and then add ammonia gradually, with constant stirring till all is dissolved, taking care to employ as little as possible, or the colour will be too deep. It is not generally known that the addition of a few drops of ammonia to a spirituous solution of shellac will render it completely miscible with water in all proportions without precipitation. This property is very useful in removing the varnish from a negative by alcohol, as it prevents any deposit from precipitation when the alcohol is removed by washing.

In dissolving shellac in alcohol the great difficulty is to clarify the solution, and the drawback is the great waste of solvent which is imprisoned by the flocculent insoluble matter always found in alcoholic solutions of lac. The addition of chalk and magnesia is often recommended to reduce the cloudiness of the solution, which, however, it is stated, soon returns after the use of these materials, although it be well filtered. It is further said that with stick or seed lac the effect is not so prominent.

This milkiness or flocculent deposit is evidently the effect of the undissolved constituent of the lac, the wax we have described forming one of its component parts. Many methods have been devised for getting rid of it, but that of Herr Andes, which we have spoken of, is based on the insolubility of the wax in carbonated alkalies, though lac itself is quickly dissolved. This being the case, Herr Andes sets the lac to dissolve in a hot solution of carbonate of soda, and then, after the whole has cooled, he removes the cake of wax which has formed in the surface of the cold solution. The soda, being neutralised carefully by sulphuric acid, throws down the lac again in a purified form. It is, however, said to be lowered in quality and made brittle in texture; in other words, to have lost its essential character of hardness and toughness.

In our opinion all processes which tend to the entire removal of the "wax" are a mistake; for we believe it is to the mixture of all its constituent ingredients, and not any particular one, that shellac owes its great value, and that if any one of them be removed the whole mass suffers. We, of course, leave out of consideration the colouring matter, whose presence *per se* we do not suppose to confer any advantage.

Where it is desired to obtain a clear alcoholic solution of lac it may be made by adding to the alcohol one-fourth of its bulk of petroleum spirit, frequently shaking for an hour or two till dissolved. Two layers of liquid will form after a time, and they can be readily separated from one another by means of a syphon or a separating funnel. The upper layer of liquid is the petroleum spirit with the wax dissolved, while the lower is the resinous constituent dissolved in alcohol. A similar effect is obtained by first shaking the shellac up with warm petroleum spirit before dissolving in spirit. The shellac has to be coarsely powdered for the purpose, and a troublesome task it is to perform. Those who wish to try it can, however, buy powdered shellac, which is largely used for pyrotechnical purposes.

The great staple lac for photographic use is undoubtedly "white-lac," originally devised in the days when sealing-wax was an article of great demand, the process of decolorisation leaving it in a form adapted for using with the most delicate colours. For this purpose it is, or was, made on a very large scale. Gmelin gives the following as a method for producing a perfectly white shellac soluble entirely in alcohol:—"Twenty-five parts of shellac are dissolved in six hundred parts of water containing ten parts of soda, and the solution is mixed with dilute hypochlorite of soda, and then with hydrochloric acid as long as the precipitate redissolves. It is then exposed to the sun for a day or two, mixed with sulphite of soda, and precipitated by hydrochloric acid." We do not doubt that anyone giving this method a trial will feel as fully satisfied with the result in appearance and working qualities as is possible with a white lac.

Our own experience, however, with white shellac of commerce is that in the process of bleaching it has lost much of its valuable quality; for a varnish made entirely with it is far less tough or hard. It may comparatively be easily scratched with the finger nail, while orange shellac dissolved in spirit never can be. We may say that we have tried to reduce the colour of a sample by means of charcoal and exposure to sunlight, as recommended in some works; but we have been entirely foiled, scarce a trace of colour having been destroyed after a continuation of the most vigorous daily shakings. We may observe, too, that old experiments of our own in dissolving shellac in ammonia and then endeavouring to decolorise by means of chemicals other than chlorine, followed by precipitation of the resin, never gave us any satisfactory results. When we have required a lac varnish we have used a solution of both white and orange lac mixed, obtaining results which it would be most difficult to surpass in usefulness, and with so little extra colour from the orange lac that no inconvenience was caused.

We may conclude by pointing out to those of our readers who are not aware of it an important property of white lac:—Although shellac retains its power of solubility in alcohol for an indefinite period, white lac, on the contrary, will gradually lose its solubility until in time it will become as insoluble as stone. The best way to preserve its qualities is to keep it covered with water, which will greatly prolong its keeping powers without in any way injuring its properties.

A correspondent from Wanganui, New Zealand, Mr. W. J. Harding, gives us in a private letter the following method of reducing over-dense negatives. He says:—"I find by practice that a gelatine unvarnished negative, when dry, may be reduced to any extent, either all over or in any part, by rubbing it with a piece of rag wetted with methylated spirits. The rag becomes black as if with indian-ink. I now reduce the over-intense iron roofs of buildings in that way, and am very pleased with the result."

The same gentleman says, in connection with our friend Mr. Andrew Pringle's last series of articles:—"I very much liked *Round the World*, by Andrew Pringle; but we have no trouble to get the Maories to sit for portraits in these parts. The trouble is to keep them out of the studio, and I don't find them *too* honest." Accompanying Mr. Harding's letter are some two or three dozen portraits of Maories, male and female. From a careful examination of these we judge that the New Zealand "lines of beauty" differ somewhat from ours.

What funny people some of our new-world contemporaries are to be sure! In a leading article in one (which is now in the twenty-first year of its existence), entitled *Our Influence*, it waxes quite jubilant that what has been designated the "fifth quarter" of the world "has quite a list by herself, twenty-six subscribers being supplied there every month." After proclaiming the fact that a new subscriber has been received through Sampson Low and Co., of London, it heralds the fact of its California agent increasing the number of its patrons to fourteen! Those acquainted with the *trade* in this country will conclude that some brethren are thankful, and properly so, for very small mercies.

From the same journal we perceive that punning of a certain class is now beginning to pervade the photographic literature of Pennsylvania. For example:—"What a fearful punster is brother Allen, of Detroit. He is Orville (awful). Is a key required?"——We venture to say that a key *is* required.

The friends of Mr. George H. Croughton, formerly of Lowestoft, will be interested in learning that he has become a regular contributor to our Philadelphia contemporary. Mr. Croughton is now a resident in the American city of "Brotherly Love."

From the contemporary just referred to we learn that "most of the photographers on the Ohio River, from Pittsburg to Cairo, were submerged more or less by the flood." We have not heard of any of them having been drowned, but we sympathise with them none the less, whether the submergence were in whole or in part, or whether it was the photographers themselves, "their ox, or their ass, or anything belonging to them," that was "submerged."

Who was it that, in the course of a paper read before the South London Photographic Society, last year, on photography in America, spoke in such eulogistic terms of the glorious and bright weather of the New World in contrast with that of "Perfidious Albion?" And how must he feel when he reads the following from the leader page of a local journal which ought to know?—"Business, since the first of January, has not been the best. In most localities bad weather has been the rule, and sunlight the exception. Throughout the Ohio Valley unprecedented rains have prevailed, and some photographers have not, on the first of March, been able to get off some of their Christmas work." In what respects, therefore, are meteorological conditions more favourable for the operations of the photographer in America than in England?

At the last meeting of the Association of Operative Photographers of New York the following curious statement was made by "A Member":—"The English, he found, had gone back to oxalate; he himself had gone back to pyro." This will, indeed, be news to the majority of "the English" for more reasons than one. First, the statement implies that the oxalate developer was the first used on this side, and that photographers had seceded from that to pyro.; whereas, as a fact, alkaline pyro. was in general use at least fifteen years before oxalate was heard of. Secondly, the statement would lead one to suppose that ferrous oxalate was, or had been, at some time the favourite form of developer amongst English photographers—a conclusion so singularly contrary to fact that we wonder at anyone who even occasionally sees an English journal venturing to make such an assertion.

The fact is that pyro. has always been the favourite developer with the majority, and we expect always will be. Further than this: many of those who at one time used oxalate exclusively, on account of its simplicity and the character of negative it gives, have since learning the value of pyro. adopted that method in preference. Indeed, from the report of the meeting alluded to, we find that that is becoming the case even in American plates, where oxalate had become firmly established. As the quality of American plates improves with experience in manufacture so will the use of pyro. increase; for, as Dr. Liesegang said at the Photographic Club, in explanation of the greater popularity of ferrous oxalate on the continent, the English plates are the only ones that will stand pyro. development without green and other fog.

After a series of experiments with glass of various colours for dark-room illumination, Mr. G. G. Rockwood, the well-known photographer, of New York, has decided in favour of a combination of orange, green, and ground glass, as giving in the highest degree safety, comfort, and quantity of illumination.

Our old friend, Mr. P. Mawdsley, has been discoursing before the Rochester (N. Y.) Photographic Association on the subject of stops in landscape photography. His view is that by using too small a stop atmospheric effect is destroyed; hence he advises the employment of as large an aperture as may be compatible with definition.

Mr. Edgeworth, of the Chicago Amateur Photographers' Club, has some novel notions on the subject of development. We learn from *The Eye* that "by using the developer with dry pyro. you would not get negatives with stains;" and that "in the developer of the two sodas there was no ammonia used." But the most surprising result of his experience is that "the finest accelerator, in his opinion, was water—*of course it developed alone.*". The italics are ours.

The explanation of the "dry pyro." developer and the "developer of the two sodas" is found in another paragraph of the same report, where Mr. Edgeworth gives his formula. He says:—For the pyro. solution take as follows: salicylic acid six grains, to one ounce of pyro. The accelerator was composed of carbonate and sulphate of soda. He found it work well; it gave no stains." But he omits to say

PAYNE JENNINGS.

INK-PHOTO. SPRAGUE & Co LONDON.

whether the salicylic acid is to be dissolved in the pyro. or the pyro. in the salicylic acid; nor does he explain why "the finest accelerator, in his opinion"—water—is entirely dispensed with.

A book of some interest has been published by Messrs. J. Wilson and Son, University Press, Cambridge, Mass., entitled *Researches on Astronomical Spectrum Photographs of the late Professor Henry Draper, M.D.* It consists of extracts from the *Proceedings* of the American Academy of Sciences, and contains cullings from the original notebooks and an introduction by Professor C. A. Young, with measurements and discussions of the plates by Professor E. C. Pickering. Although quite recently spectrum photography has made great advances, an account of the work done by Professor Draper in connection with this subject, with which his name is inseparably connected, will be of great value.

We have already dwelt upon the probable future usefulness of Willesden paper in connection with photographic work—mainly, perhaps, building work; but with regard to indoor requirements we cannot help thinking it remarkable that greater attention has not been given to the advantages of "built-up wood"—the peculiar sheets made by glueing together pieces of so-called "veneers." The material is, perhaps, most familiar in the form of chair seats—semi-elastic wooden slabs perforated with a number of small holes; but it is produced in many forms, and of plain and ornamental woods. It is made by well glueing sheet upon sheet of wood together, the grain of one being crosswise to the next; and when each sheet is nearly saturated the whole is submitted to hydraulic pressure which welds it almost into a homogeneous sheet without cleavage and without possibility of splitting. The inside can be of inferior, the outside of ornamental, wood; and, as it is economical, strong in every direction, and impossible to be cracked, it possesses advantages of strength and permanence which should make it very valuable for many photographic purposes. As an example of the wide range to which its usefulness can extend, we may instance canvas for artists and binders' boards for book covers, for which it has been found an efficient substitute.

Professor Bryce's bill "to secure access to the mountains and moorlands of Scotland" ought to secure a hearty meed of praise from the whole body of tourist photographers in the north, as great restrictions have been placed on the access to some of the most beautiful haunts of the lover of nature—"trespassers beware!" staring him in the face in all directions. The bill embodies every possible precaution against the abuse of the access craved. We join in the wish expressed by a scientific contemporary that all interested societies "should use every legitimate means to obtain for it parliamentry sanction."

Quilla bark is a very singular natural product—an infusion forming a mixture possessing many qualities analogous to those of a solution of soap, among them that of forming a permanent lather. Saponine is an active principle obtained from this substance, and appears to possess properties that may render it serviceable in photographic operations. Stütz could not prepare it in a pure form, but Schiaparelli states that he has been able to produce a perfectly-pure sample free from all inorganic substances. He states that it has the property of preventing the separation of substances insoluble in water, and that a solution of "soap bark may be looked upon as a semi-emulsifying medium." We have no data available to know its exact *modus operandi;* but though there are many agents—such as gelatine, sugar, and other substances—which also possess the power of interfering with the precipitation of insoluble matter, saponine may have a place in photographic operations.

According to a technical journal, "Mr. St. George has devised a method of recording telephonic communications by means of photography. This is done through the action of a circular collodion-covered plate, which revolves by clockwork. A pencil of light vibrates through a small slit, and leaves a dark line on the plate. The record of these vibrations is afterwards fixed in the ordinary manner."

The following is given as an excellent formula for making an etching ink for writing upon glass:—Equal parts of sulphate of barium and fluoride of ammonium are mixed in a lead vessel, and sufficient hydrofluoric acid is added to form a thickish liquid with which glass can be written upon with a steel pen. This etching ink should be allowed to remain for about half-an-hour before being washed off.

As iodine still finds a place on the shelves of the photographer's laboratory, it may be well to note the best method of encountering it if by any chance some should be swallowed by mistake. The usual effect of a poisonous dose of this chemical is the production of so much irritation of the stomach as to cause sufficient vomiting to eject the greater part of its contents. A German technical journal, commenting on a recent case of poisoning by iodine, puts forward starch paste as the best antidote under the circumstances; but it would certainly appear that "hypo.," which was actually used in the case in question, is much more likely to be useful, as the chemical change it would bring about would result in the production of a comparatively inert compound.

The second volume of the *Calendar of Documents Relating to Scotland* in H.M. Public Record Office is in the press, and will shortly be published. One of its distinguishing features, which the *Athenæum* justly characterises as of great value, will be the autotypes of a considerable number of homage seals. Photography is considerably cheaper than engraving, and is infinitely superior to it for the purpose, seals and coins being reproduced by photography with, of course, unerring fidelity, and, at the same time, with such verisimilitude of representation that the eye can often be deceived, a casual inspection giving the effect of true relief.

When shall we be able to have lumps of solid oxygen? The other day Professor Landolt exhibited to the Physical Society of Berlin a cylinder of solid carbonic acid which had been made upwards of an hour before he produced it. He allowed liquid carbonic acid to enter a cloth bag in which, through the quick evaporation, it took the form of a loose snow, which was then hammered into a mass in a cylindrical cylinder.

By-the-bye, liquid sulphurous acid, always a favourite material with experimentalists for producing intense cold, appears now to be in great demand—at least so we judge from the fact that it is advertised as a regular article of commerce, to be bought at so much per pound.

Works of art—the term including photographs—imported into America are subjected to a very heavy duty, on the principle, we suppose, that being luxuries, they should be taxed at a high rate. Formerly the rate was ten per cent. *ad valorem;* the Tariff Act of last year raised it to thirty, and the late Tariff Commission recommended its being raised to forty per cent.! There is, however, another side to the question, that of the educational and refining influence of pictures and sculptures, and some American statesmen hold that their value on that account should secure their introduction duty free; fortunately the question is not complicated with ideas of "protection," for the American artists themselves ardently support duty-free importation of pictures. The feeling of the country will be put to the test, for Representative Perry, of New York, has now introduced a bill which, if passed, would admit, without any duty being paid, all works of art, ancient or modern, the term to be construed as including all "paintings, drawings, and photographs, as well as statues of marble or other stone." The breadth of mind which such a measure proves must be gratifying to all true lovers of art, and it is to be sincerely hoped that the bill may pass in its entirety.

MR. PAYNE JENNINGS.

The subject of our illustration this week has been well known for his artistic landscape work for many years past—not only in this country, but also on the continent and in America. His first success was scored in Ireland, his Killarney series of pictures, published about fourteen or fifteen years ago, attracting universal attention by their freshness and novelty of style, as well as their technical and artistic merits. Other portions of Ireland, the Lake District, and Great Britain generally, have since occupied Mr. Jennings's attention, and he has figured frequently as a medallist at different exhibitions as well as in the capacity of judge, for which post his technical knowledge and artistic taste eminently fit him. Few figures are better known at the London meetings than Mr. Jennings's, as he is at present, or as been, on the executive of the

Photographic Society of Great Britain, the South London Photographic Society, and the Photographic Club, of which last he was one of the original committee.

THE FOCAL LENGTH OF LENSES FOR LARGE PORTRAITS.

I READ with great pleasure the article in your last issue on *Lenses for Large Portraits.* I am particularly glad to see that photographers in general are beginning to understand a little more than they formerly did the functions of the principal instruments of their work, and that they are coming to appreciate the fact that, if they work with a lens stopped down to give a certain angular aperture, the smaller in diameter the lens itself is the better. Only a couple of years since I remember at a photographic meeting there was brought up a subject very similar to that which was treated at the recent meeting of the Photographic Club, and that the general opinion of members was that, used with the same angular aperture as a lens of the "rapid" landscape type, the portrait lens had some peculiar virtue of its own which was variously, but somewhat indefinitely, described as "penetration," "intensity of action," "roundness of image," and soforth.

Now, as a matter of fact, if these phrases have any meaning at all, they describe properties which the portrait lens possesses in a less degree than any other. Thus, "penetration" is a word which may describe a property of a lens in giving the least possible amount of diffused light in the camera, thus allowing deeper shadows to be rendered with strong detail than would otherwise be possible. This property is possessed in the highest degree by such lenses as have the fewest reflecting surfaces. Thus, the single lens exhibits it in the highest degree possible in any lens, as it has but two reflecting surfaces. The lenses of the double combination type with both combinations cemented, which includes all English landscape lenses of the "rapid" type, come next; whilst at the foot of the list comes the portrait lens with its six reflecting surfaces.

May I venture to say that I believe the "universal" or group lens is the best for large portraits only up to a comparatively-moderate size, and that for very large sizes the "rapid" lens is by far the best. From what I gather of the practice of the best portrait photographers it is seldom that in the case of plates measuring sixteen to twenty inches in length an aperture of more than about $\frac{f}{10}$ or $\frac{f}{12}$ is used, whilst I understand that $\frac{f}{16}$ or even $\frac{f}{20}$ is not uncommon. Now, all these apertures can easily be got in the case of a lens of the rapid rectilinear or rapid symmetrical type.

The special point on which I wish to say a few words is one which has, I think, been overlooked by the Editors in the article I referred to at the beginning of this communication, and which is, indeed, one very often overlooked by photographers generally. I refer to the increase of focal length which takes place in a lens when it is brought at all near the subject to be photographed.

In giving the focal length of lenses manufacturers always state the length of focus when a distant subject is photographed. Now, as we well know, in the case of portraiture the object is never distant. The increase of focus beyond that for a distant object which takes place when we focus for a portrait is a small fraction of the focal length in the case of short-focus lenses, but it is by no means inconsiderable in the case of a long-focus lens.

As you justly remark—"It has been generally conceded that to obtain the most pleasing results in portraiture . . . the longest dimension of the picture should in no case exceed one-half the focal length of the lens with which it is taken." This is very true, but the rule applies not to the focal length of the lens when a distant object is focussed, but when the portrait to be taken is itself focussed. This gives us, in the case of very long-focus lenses, such an increase of focal length that in using them on the plates which they are advertised to cover we do not fall very far short of what is demanded by the above rule.

The formula for calculating the increase of focal length of a lens, when a near object is focussed, is very simple. Let f be the focal length of the lens for distant objects. Let n be the number of times smaller that the ground glass image is than the object itself; then for that particular image the focal length will be $\frac{n+1}{n} \times f$.

We may put the manner of using this formula in words in the following manner:—Discover how many times smaller the image on the ground glass is than the figure being photographed. Divide the focal length (for a distant object) by the figure thus obtained. Add to the focal length for a distant object the figure got by this division, and we shall have the focal length for the near object. This requires illustrating, and I shall take the case of the lens which the Editors mention in the article referred to. This is a lens of twenty-eight inches equivalent focus, which is to be used for covering a plate 20 × 16 inches.

Suppose that the standing figure of a very tall man is being treated. This will give the smallest benefit in the way of increase of focal length that we ever get in the case of portraiture, and yet this increase will be by no means inconsiderable. Probably about fifteen inches of the plate will be occupied by the figure. Supposing the man to stand six feet three inches, the image will be exactly five times smaller than the object. We, therefore, divide the focal length (twenty-eight inches) by five. This gives, as near as possible, five and a-half inches. This, added to the focal length, makes thirty-three and a-half inches—certainly still a good deal short of the forty inches required; but then it must be borne in mind that a standing figure, being nearly in one flame, there is not likely to be much noticeable straining of perspective.

Worked out according to the formula that I have just stated, this comes out as follows:—$\frac{5+1}{5} \times 28$ or $\frac{6}{5} \times 28$, which, worked out, gives precisely 33·6 inches.

In the case of a sitting figure, in which the perspective is most liable to be strained on account of the fact that parts of the subject are much nearer the camera than others, we have a much greater advantage. A very tall figure measures, when sitting in an ordinary chair, four feet four inches in height. This will again occupy about fifteen inches of a 20×16 inch plate. Fifteen inches is within a small fraction three and a-half times less than four feet four inches. Taking the formula again, we have—$\frac{3\frac{1}{2}+1}{3\frac{1}{2}} \times 28$. This, worked out, gives thirty-six inches. We are now very nearly approaching the required focal length, which ought to be twice the length of the picture. It should be borne in mind that from a 20 × 16 inch plate we shall probably not get a picture more than nineteen inches long; therefore all the focal length that we require is double that, or thirty-eight inches. In taking head-and-shoulder portraits, which will come out on a 20×16 inch plate at least half size, we find our focal length increased to forty-two inches, or considerably more than the greatest which can be desired.

Taking all this into consideration, I think it will be granted that, so far at anyrate as perspective is concerned, the opticians are excusable in advertising their longer-focus lenses as capable of covering a plate proportionately longer than their smaller ones do. Possibly they carry this affair a little too far.

Surely, however, there is no excuse for an optician who in his lists mentions the back focus of the lenses advertised without making any mention of the equivalent focus. A knowledge of the back focus of a lens conveys absolutely *no* definite information to a purchaser. Surely this is a matter in which our opticians might with advantage recast their price lists.

There is another point in which I think they might make an improvement. Why is it, I wonder, that our leading opticians still describe the properties and capabilities of their lenses in the same terms which were applied to them when they were to be used for wet plates only, but which in many cases do not correctly describe their capabilities when used on dry plates? Surely it is not with the view if imposing on ignorant customers by persuading them to purchase the expensive portrait lens, when a cheaper lens would much better suit their purposes.

W. K. BURTON.

A RAPID EMULSION FORMULA.

I SEND you a formula which I find excellent and very rapid. It is very simple, and an emulsion can be prepared in a few minutes:—

Stock Solution No. 1.

In ten ounces of distilled water dissolve—

Bromide of ammonium	560 grains.
" potassium	960 "
Iodide "	80 "
Chloride of ammonium	200 "

Solution No. 2.

Absolute alcohol	10 ounces
Liquor ammonia (strong)	$3\frac{1}{4}$ "

Solution No. 3.

Distilled water	10 ounces
Nitrate of silver	750 grains.

In one ounce of No. 1 dissolve ten grains of gelatine by gentle heat; then add three ounces of No. 2 and three ounces of No. 3, shaking whilst adding the solutions. Then add five drachms of dry gelatine and dissolve by gentle heat. After complete solution pour it into fifteen ounces of warm methylated alcohol, cool, and place the cake of emulsion in a mixture of—

Glycerine	5 ounces,
Absolute alcohol	5 „
Thymol	5 grains,

which will keep it indefinitely. AJAX.

THE LIME LIGHT.

"IN the multitude of counsellors there is safety." So says the scripture adage; and as I have, in conjunction with Mr. Robert M. C. James, of Watford, and Mr. Steward's lime-light jet maker, conducted a number of experiments with a view to obtaining improved results in lighting, I will, with your permission, offer a few remarks on the same.

The lantern employed was a Bridgman triple, with lenses as nearly as possible alike for focus, colour of glass, &c. The gas was in gas-holders and in bags. A photometric slide was put in each stage of the lantern, and consisted of a disc of brass fitted into a mahogany block of the ordinary size, but very carefully made and centered. A section of one-third of the circles (three and a-half inches) was cut out of each in such a way that one-third of the disc was illuminated by each lantern, and so an entire circle made up, each plate being marked distinctly, so that a reference to degrees of illumination could be quickly made.

In the first experiment No. I. jet had a nipple with a comparatively large orifice, and the nozzle bent considerably, so as to concentrate on a spot. No. II. had the same-sized nipple, but the nozzle was straighter, so as to give an elongated incandescent area of light. No. III. was a small nipple, and was supplied from a twelve-feet oxygen and a fifteen-feet hydrogen gas-holder without any other pressure than the weight of the dome. Nos. I. and II. were supplied from gas bags in a double board with fifty-six pounds pressure.

The result, as shown on the screen, was that No. III. was superior to No. II., and both were much in advance of No. I. in brilliancy. The conclusion we came to at this trial, and that which I think we fairly demonstrated, was that the light should not be a spot, and the orifice of the nipple should not be large when using a small pressure. With the hydrogen tap full on in each instance I noticed that, with the light at the best point attainable, the oxygen tap No. I. was only one-third on, in No. II. was half on, and in No. III was two-thirds on. To see what relation there would be in the light by increasing the pressure on the bags and leaving the gas-holder as it was, all the jets being precisely as before, two additional fifty-six pounds weight were added, making one and a-half hundredweight, with the result that No. II. was increased so much that it was cent. per cent. better than No. III. (the previous best), and No. I (the worst previously) was slightly better than No. III. Conclusion come to:—The larger-sized orifice was available for a high pressure with satisfactory results, thus proving the aperture or orifice of the nipple must be regulated by the pressure. The maximum light to be obtained without noise could only be ascertained by actual experiment.

A number of other trials were made with a view of overcoming hissing and waving of light, the nipples being successively larger, and tried on short nozzles, long nozzles of ordinary form, long swan-neck nozzles, and so on; but it was found that, no matter how carefully they were broached and made, the moment the orifice passed a certain aperture with a certain pressure the hissing commenced.

The subject of *safety-valves* and chambers also engaged our serious attention then, and very considerably since the Chadderton explosion, and the form that commended itself most to us was Highley's water interceptors. Those, however, we made in accordance with his description and drawings, we found, were not practical, for two reasons—first, serious diminution of pressure; second, waving of the light. After a number of experiments and modification of old forms of valves and entirely new valves had been tried, we reduced to a working minimum the loss of pressure; but up to this time have failed to get over the fluctuations in the light after the gas has passed through the interceptor (and consequently through the water) to the jet. I may mention that some two dozen different forms of vessels have been constructed of tall, short, and broad make, and fitted with everything that ourselves and the gas engineers we have consulted could suggest, and we have not yet found the right thing for *practical* work, although our approach to it at times has been so near that we thought the goal had been reached. Although checked, we do not consider ourselves quite *hors de combat*, and shall go at the enemy, "hidden danger," as soon as some fertile imagination can start another convoy of ammunition in the shape of ideas. It will be very encouraging to the lanternist and everyone using explosive gases if an *absolute* safety-valve can be devised; and I hope that Mr. Broughton or some of your correspondents will be able to demonstrate that no explosion is possible when using pumice chambers, and that they do not practically affect the light.

I notice, in your issue of April 11, that the Rev. T. F. Hardwich has tried these pumice chambers, and his test for safety seems a very fair one. I shall be glad if he can kindly tell us what percentage of pressure is lost by passing through them, and if he has tried them with the most explosive form of mixed oxygen and hydrogen he can make. I can endorse his opinion that oiled silk valves are no use to stop *ignited* gas returning; and, from what the Editors and other experts say, even such material as plaster of Paris and wood will not stop it. I am trying some new metallic and non-inflammable valves of a simple kind that have occurred to me, and if the results are at all of value I will communicate the same to your excellent Journal.

Unequal Pressure.—Our experience of unequal pressure is this—that there is no danger while both are forward, even if that on one bag or holder be three times as great as that on the other, the taps of jets sufficiently regulating the supply correctly. If anything be wrong it will be indicated by the light, and it is wisest to at once turn off the gases and make a general inspection.

Gas Dissolvers.—I find that among a great number of lanternists the gas dissolvers are very little understood, and unless the principle on which they work be mastered I can readily understand the hitches occurring that we hear and read of. I would strongly advise a periodical inspection of the dissolvers, as the grooves of plugs may be partially stopped by the lubricant, or the chlorine deposited by the oxygen. Screws that secure the plug should not alter by the working of the plug, as I have known them to do, and so cause the plug to become loose and the gas pass round it.

Jets.—As most jets take to pieces, great care must be taken to see that all the joints are sound. In the interchangeable and other forms of jets where the nozzle removes, a little grease to the ground fittings is occasionally required; and if there are any washers they must be sound to secure a gas-tight fitting. The popping-out of light after or during dissolving is sometimes attributable to a leakage in the jet. To test if a jet or chamber, such as a retort, purifier, &c., is gas-tight, stop up by turning off the taps or plugging with the finger, a cork, &c., all outlets except one, and then try and create a vacuum by sucking. If on the outlet touching the lip, it hold fast, it will be sound enough for all practical purposes. Another cause of occasional popping-out of the light is having too large an aperture in the nipple of the jet. If everything else be right with the jet and dissolvers, and the light go out with a report, the most likely thing is that the gases are not properly combining, and so they explode when the oxygen gets sufficiently in excess in the jet or pipes. G. R. BAKER.

TRACING ON GLASS FOR THE LANTERN.

SOME four or five years ago, possibly more, I gave, in one of the almanacs, a process for tracing designs on glass for the lantern, which, if it had only been followed up, would, I am sure, have been much in use at the present day, and such things as ground glass *à la* transparent slate, and other like systems would be put entirely in the shade. It was simply a varnish composed of dammar in benzole or chloroform, to which a few drops of india-rubber solution had been added. After an hour's drying, it was ready for use. With a fine lithographic pen dipped in indian-ink the finest drawing can be executed. I have myself written my name in full, "Walter Bentley Woodbury," in the diameter of a fourpenny piece; and by means of a small piece of damped card attached temporarily, have by the aid of drawing instruments, made some fifty circles in the space of a couple of inches. The advantages are that the glass is perfectly transparent, and even under a high power the lines show no sign of raggedness.

I should be glad if some of your readers, interested in this work, would give it a trial and report on it—*pro bono publico.*

W. B. WOODBURY.

THE LATE MR. F. A. WENDEROTH.

IT is over twenty years since articles of a brief yet practical nature began to be contributed to this Journal by Mr. F. A. Wenderoth, of Philadelphia, who was at that time, unless we are misinformed, a member of the photographic firm of Wenderoth, Taylor, and Brown. It is with much regret that we have to record the death of this gentleman—an event which took place on the 15th ult. A native of Germany, Mr. Wenderoth emigrated to America when he was thirty-five years of age, residing at first, and for several years, in California. He afterwards, in or about 1857, settled in Philadelphia.

Although he was an able practical photographer, his predilections lay most strongly in its artistic development. We possess examples of his more purely pictorial photographic work, which are perfect masterpieces of posing and artistic conception as regards grouping of figures. He was specially successful in a system of printing on opal glass originated by himself, and for instructions in which he refused the offer of large sums, afraid lest it might fall into the hands of those who would lower and cheapen a class of work for which he entertained so high a regard. The stripping and transferring of collodion films, ghosts in the solar camera, flare in lenses, the angle of view, the enamelling of photographs, the production and painting of opalotypes—these are among the numerous subjects upon which he wrote. In later years he devoted himself almost entirely to art rather than to technical photography.

So far as we can learn, Mr. Wenderoth was slightly over sixty years of age when he died. His latest contribution to our Old World literature was an article by him in our ALMANAC for 1880. He leaves a widow and grown up family.

PHOTOMICROGRAPHY.

[A communication to the Glasgow and West of Scotland Amateur Photographic Association.]

THOSE who use the microscope for the study of natural history are fully alive to the value of photography as a means of registering their observations, but the great majority are deterred from attempting its use by the idea that it is difficult as regards manipulation, and costly as regards apparatus. The various text-books of microscopy are greatly to blame for this, and certainly their descriptions of heliostats, electric lamps, and special microscopes are alarming. I hope, however, to show you that, in these days of dry plates, much may be done with very simple apparatus and little trouble.

There are microscopists whose interest lies rather in raising the microscope to the highest pitch of optical perfection than in its use for the purpose of study; and, doubtless, with the enormous magnifying powers now at their command, manipulation does become difficult and apparatus costly when they call in the aid of photography to test the latest optical triumph. The other and larger class, who in pursuit of knowledge use the microscope only as a tool necessary for their work, would welcome photomicrographs for their indisputable truth and manifest advantages over *camera-lucida* drawings. For such work as they require you see here all that is necessary—a good, firm, microscope, a "Lancaster" quarter-plate camera, with dark slides (the lens of course is removed), and a source of light, which in this instance is a magic lantern, although a paraffine lamp will do as well. The condenser between the lantern and object is the "bull's-eye" provided with every microscope. The body of the microscope should be short, if possible. Mine, as you see, has a short body with sliding-tube for lengthening. As this tube contains a diaphragm which would lessen the field if used full length, I keep it pushed in, and make up the length by means of this wider tube on the camera front. A pasteboard tube well blackened would do for this purpose. It is advisable that there should not be a rigid connection betwixt the microscope and the camera, as putting the dark slide in place might disturb the focus. The eyepiece, as a rule, is removed, though very minute objects may require its use, but then the loss of light is enormous.

Microscopic lenses, or "objectives," are in all good microscopes achromatic combinations, and may be divided into two classes—wide angle and ordinary. The first have greater resolving power—that is, the power of showing minute details of structure which might escape the narrower-angle objectives; but, on the other hand, these latter have more penetrating power or "depth of focus," and when the object is of appreciable thickness will show with comparative sharpness parts lying in different planes. This is the more fortunate, since the ordinary lenses are much less costly than those of wide angle, and are the class generally supplied with so called "college" or "medical" microscopes.

Here is the lens I find most useful. It is called a "one-inch objective," and is so called because it has the magnifying power of a single lens of one-inch focal length. To increase its penetration I have reduced its aperture by one-half with a paper diaphragm, and have still plenty of light. Here is one of a-quarter-inch focus much more powerful. Here is another, to which I would direct your special attention. It is now of one and a-half inch power, but by turning this collar I can decrease its power by degrees to four and a-half inches. This means that a comparatively-large object may be viewed as a whole and magnified a few diameters, and then, the power being increased, it may be examined in detail. There is a scale on the revolving collar for registering the power employed. In photography this lens is remarkably useful, as the object can be enlarged just sufficiently to cover the focussing-screen. It is, however, only available for comparatively-large objects.

I should like to ask any of our members who are well up in optics if there be any reason why we should not have a variable lens like this for landscape work. It would be peculiarly useful to us in the West of Scotland, where at one time we are doing a "bit" in a glen with most of the picture within a few yards of the camera, and next minute have to deal with hills ten miles away. Under these circumstances a lens of variable focal length would be very desirable.

The greatest difficulty in photomicrography is to judge exposure. It varies with every objective and with every object. The thickness, and particularly the colour, of the preparation must be considered. Parts of insects are, as a rule, of a reddish-brown tint, very non-actinic, and require long exposures; while botanical preparations are generally colourless or green, and require much less time. As a rule, with an object which is new to me I give an exposure which I know must be full, and develope with hydrokinone, using a minimum of sodium carbonate to begin with. The image comes up very slowly and is perfectly under control. When I know the right exposure I give it, and use Edwards's developer, which seems to give a very fine grain to the negative. Too much density should be avoided, as it is often desirable to make lantern transparencies or gelatino-bromide prints from micro-negatives, and for such work a rather thin negative with lots of detail is best.

It is generally stated in works on microscopy that the chemical and visual foci of objectives do not coincide, and that, after focussing, the objective should be moved closer to the object to an extent only to be found by experiment. This is doubtless true in theory, but so far as any of my lenses are concerned I have found that a sharply-focussed image gives a sharp negative. It will, however, be found that when using a low power the objective may be moved through a very minute fraction of an inch on each side of the point of absolute sharpness without apparent detriment to the image. In such a case it is advisable that it should be moved to the nearest point to the object consistent with sharpness; it will then be in focus for the blue rays.

My subject may not be of much interest to most of you, but after seeing the operation of making a photomicrograph you may be able to convince some doubting friend that it is not so very difficult after all. It is interesting to note, by the way, that probably the first gelatino-bromide plates were used for this work, since Dr. Maddox, to whom I believe we owe the process, is an eminent microscopist and uses photography largely in his researches.

The apparatus I have shown you is simple and inexpensive enough, but good work may be done with a home-made camera. My first attempts were made with a curious-looking affair made from some old boxes and a bit of black velvet, and were quite successful. I found, however, that some objects required direct sunlight to do them justice, and then a well-made camera and dark slide are assuredly necessary. To give you an idea of the exposures necessary I shall now take some negatives. WM. GOODWIN.

A BALLOON TRIP.

IN our issue of last week we announced that Mr. Cecil V. Shadbolt intended to make two ascents in the "Sunbeam," on Monday and Tuesday last. These aërial trips were to take place from Birmingham. The first actually took place on Easter Monday. At the last moment we have received the details of the start and ascent, which are so graphically described in Mr. Shadbolt's communication that we give the particulars in that gentleman's own words:—

I will tell you in very few words how I got on—or, perhaps, you will think, did *not* get on—on Monday last down at Birmingham. The fact is, I have had such a taste of the "shady side" of ballooning that I should be sorry to have a similar experience again if it could be avoided; but, at the same time, of course we must just take all these things as they come, if we want to do any good—the rough as well as the smooth.

The wind was so high at the start that the balloon could not be got under control, and, after being dragged about by an immense crowd of people who were assisting us in the hope of getting something like a decent start, we were obliged to let go everything and get dragged along the ground through the immense throng of people who were present, and who made way pretty quickly before us. Bag after bag of ballast was thrown bodily out, and at length we rose beautifully without injuring anybody, which seemed rather astonishing under the circumstances. Mr. Dale was at one time thrown clean out of the car, but fortunately regained it in safety before we soared aloft. The journey itself I need not describe, save that we reached an altitude of just upon 5,500 feet, and lost sight of the earth for a considerable time.

In cloudland all was, of course, calm and peaceful, and we seemed to be hanging quite still in a scene of arctic beauty, although, in reality, we were scudding along before the wind at a speed of something between thirty and forty miles an hour. When we dipped below the clouds again we were close upon Worcester, where we landed, I am happy to say, in safety, although the concussion and subsequent knocking about was terrible, the car turning clean over and dragging on the ground in a horrible manner. Everything seemed in the most dreadful confusion. My fellow-passengers seemed right over my head, and a heavy bag of ballast fell on me from somewhere. The bottom of the car must have been up in the air at the time, and for the next moment everything seemed to be in black darkness, but only for a moment. No bones were broken, and my worthy little captain behaved admirably all through. We pulled up within about fifty to one hundred yards of the river, into which we must have gone had the grapnel not taken a firm and splendid hold in the turf.

As to photographic work, it was impossible; and the camera-holder, which had been fixed to the car by a carpenter in the most businesslike manner, was torn off "like nothing" some time before we got away even. You will not be surprised when I tell you that after this, the following day appearing equally unfavourable, I decided to "go up"—not by the "Sunbeam," but by the 11.30 train for London; and here I am, safe and sound on the whole, though rather shaken and stiff about the arms and shoulders, awaiting more favourable weather for the next ascent.

NOTES ON DEVELOPERS.

[A communication to the Leeds Photographic Society.]

I HAVE had under experiment for some time the two following questions:—"The relation between exposure and developer" and the "colour of the deposit" in negatives and transparencies. This paper may be taken as containing a few notes on certain developers which I have used in the course of my experiments, and a brief indication of the line my investigation is taking. I reserve for a future paper a more complete account of the investigation itself.

The question as to the cause of the different colours obtainable with bromide gelatine plates by the use of different developers is one which is found, on close examination, to be by no means an easy one. It resolves itself at once into two lines for observation—the colour due to simple staining as in the yellow, over-developed pyro-ammonia negative, and the green pyro. ammonia carbonate of potash negative, or the colours produced by combination of citrates, chlorides, and iodides with ferrous oxalate developers, where staining does not appear to be an important factor, if it plays a part at all.

As nearly all the formulæ described in the paper have been published, it is not necessary to repeat them. The following, however, may be included:—Take citric acid twenty grains, sulphurous acid, B. P. solution, half-drachm, water five ounces. When the citric acid has been dissolved add a quarter-ounce of pyrogallol. Use one drachm to one ounce of water for a quarter-plate. This solution will keep indefinitely. The one drachm contains as much citric and sulphurous acid as will nearly neutralise one minim of ammonia. For the ammonia solution take water five ounces, bromide of potassium forty-five or fifty grains, ammonia, ·880, half-ounce. Use one drachm to the drachm of pyro. solution, preferably adding it in separate half-drachms as the development progresses. The colour of the negative is nearly that of ferrous oxalate, and the shadows are perfectly clear.

As bearing upon hydrokinone developers, I may state that I have recently taken a very quick exposure with Reynolds and Branson's shutter, on a Nelson's ten-times plate, at half-past four on a March afternoon, the subject being a street of red brick houses and children playing. I developed with one grain of hydrokinone to one ounce of water and half-an-ounce of saturated solution of carbonate of soda. The picture came up with plenty of density and very fair detail in five minutes.

As regards the colour of the deposit: I can only say that I have so far secured a very wide series of colours with bromide plates, and that I am now carefully examining them as fast as the limited time at my disposal will allow. I have hopes that prolonged, careful, microscopical examination will throw further light upon the subject.

H. POCKLINGTON.

POITEVIN'S PHOTO-RELIEFS.

[A communication to the Glasgow Photographic Association.]

IN my former communication to the Society I made a passing reference to what the French chemist, Poitevin, had done in the way of forming relief pictures; but I was unable to bring before you any examples to illustrate his method of procedure. Since our last meeting I have made several experiments, following out, with some slight modifications, the lines laid down by Poitevin in his *Traité des Impressions Photographiques*. A copy of this work is lying on the table. It is the second edition brought out last year by M. Leon Vidal, who is, as you are aware, a no mean authority in photographic matters. Each chapter is followed by an appendix, written by M. Vidal, which adds greatly to the value of the book, and enables the reader to form a more correct estimate of the truly original nature of Poitevin's researches.

It is not only interesting, but instructive, to go over the ground traversed by the pioneers of photography; and, among the many processes that have become historical, *helioplastie*, the name given to his process by Poitevin, or sun-modelling, as it may be rendered in English, is by no means one of the least suggestive. It is simplicity itself. There are not many processes where all the development required consists in immersing the plate in cold water. When we consider that it was about the year 1848, almost forty years ago, that Poitevin conducted his experiments, the wonder is that long ere this there has not been some practical application of the work he then did. For your inspection I have here an intaglio in moist gelatine produced from a negative, and its accompanying plaster cast. Here is an electrotype, got from one of these plaster productions, which will give an infinite number of prints with gelatine ink in a Woodbury press. I have drawn one or two, just to illustrate the principle, before coming to the meeting, and they can be examined, although somewhat rough in appearance. This is due, not to any imperfection in the process, but to my not having prepared the plaster cast in a sufficiently careful manner for the delicate operation of electrotyping.

To show the difference in the nature of the reliefs obtained, when employing a positive, and when a positive picture and a negative one: here is a gelatine relief picture which has been exposed behind a positive, and with it the plaster reproduction. It seems to me some of you professional men might revive, with advantage to yourselves, these sun-modelled pictures; they would be something new, I think, to the present generation. The face as seen in profile would undoubtedly be the best pose; further, having got your plaster-mould, casts could be taken in white wax. There is no end to the many modifications that one could work out in these matters. To show how perfectly the minutest detail is preserved in these plaster pictures, here is a small landscape subject. It occurred to me that it would be interesting to try the effect of producing a plaster relief from a photograph of some statue. I accordingly got a print which you see here; it represents the goddess Hebe. Having waxed it and put it into a frame in front of a prepared film, on developing the mould presented the appearance it has here, and the plaster cast from it reproduces very fairly in bas-relief the original character of the statue. It wants, of course, the rounded character of the original figure; but perhaps, by shading the outer portions of the figure, a rounded character could be conferred on the mould, and subsequently, of course, on the plaster cast. I have not had, however, the necessary time to do anything in this direction.

I may mention that the films used in these experiments were prepared from Nelson's gelatine, one ounce to eight ounces of water, a certain amount of sugar and glycerine having been dissolved in the water. Poitevin seems to have worked with gelatine pure and simple, but you will readily understand that plates prepared thus dry badly. I dried the plates at a temperature of 90° F. or thereabouts—not exceeding it, however—in a drying-box after England's pattern. A concentrated solution of bichromate of potash was added to the warm gelatine just before coating, sufficient to give a slightly-yellowish colour to the solution. Contrary to what might be expected, a very thick film is of no advantage. In coating, I first got a level place on the table, put the plate down, and surrounded it with strips of thick plate glass, cuttings of shop window glass, arranged to form temporary slides. When set the glass was withdrawn, and the plates removed to the drying-cupboard. Filled up to the level of these thick glass sides there is always a uniform quantity of gelatine left on the plate.

WILLIAM LANG, Jun.

LANDSCAPE PHOTOGRAPHY FOR AMATEURS.

[Condensed from a paper read before the Newcastle and Northern Counties' Photographic Association.]

AT the annual lantern meeting of this Society Mr. J. P. Gibson, of Hexham, read a lengthy paper, which, unfortunately, our space does not permit us to give in full. After alluding to the capabilities of photography in various directions, and its power of expressing art feeling, he proceeded to enforce the claims of landscape photography as a health-giving and useful recreation, adding the following general directions for the use of amateurs about to take up the art for the first time:—

An expensive outfit is not by any means requisite for landscape photography. It is, I think, most convenient for an amateur to commence with a quarter-plate camera—that is, one taking photographs on plates $4\frac{1}{4}$ by $3\frac{1}{4}$ inches—as it is much less costly to work, and much more portable than those of larger size. For lady amateurs this size is specially suitable. From the negatives taken in such a camera *carte de visite* views and magic lantern slides can be got by direct printing, and by the aid of an enlarging lantern bromo-gelatine paper prints can be made, up to about 16 by 12 inches, with very good results. A portable camera of this kind, with three or four double dark slides for the prepared plates, can easily be carried in the pocket of a shooting-coat or in a very small satchel. A light stand may be got which can be used as an alpenstock in hill climbing. Such an apparatus can be had complete from about £3 to £12.

After having thoroughly mastered the technical details of dry-plate work the amateur may proceed to attempt photographs of a larger size. When the camera is required to be carried for long distances by the photographer himself without assistance a camera taking plates $7\frac{1}{2} \times 5$ inches is very convenient, as a whole-plate camera—that is, one taking views up to $8\frac{1}{2} \times 6\frac{1}{2}$ inches—is very apt to feel heavy at the close of a long day's tramp over rough country roads.

By the use of a simple adapting-back quarter-plate views can be taken in the larger camera, and with six large and six quarter-plate dark slides filled with plates the amateur is fully equipped for a long summer day's work. I prefer double dark slides to any arrangement for changing the plates during the day's work, the latter wasting time in the most valuable part of the day, and also causing a considerable risk of injury to the plates. In selecting an apparatus let the beginner carefully avoid one having many loose pieces; and before starting to work let him make out a written list of the materials required for his day's work, and carefully check it off before starting to see that he has forgotten nothing. It is a little depressing to find when miles away from home that that trifle, the lens, has been left behind. A valued friend of my own, who is one of the most enthusiastic and successful amateurs in the North of England, may be taken as a type of the forgetful photographer. He might be exactly described by a slight paraphrase of the description of the baker in Lewis Carrol's wonderfully-humourous poem, *The Hunting of the Shark.*

> "There was one who was famed for the number of things
> He forgot when he entered the ship,
> His camera, tripod, drop-shutter with springs,
> And the plates he had bought for the trip.
>
> "He had forty-two boxes all carefully packed,
> With his name painted clearly on each,
> But having forgotten to mention the fact,
> They were all left behind on the beach."

His forgetfulness (which gives him no end of trouble) is, however, equalled, or perhaps surpassed, by the wonderful mechanical ingenuity which he displays in getting out of the difficulties his lapses of memory cause, and he manages to produce charming negatives which very often tempt me to feel envious.

Coming to actual outdoor work: let me recommend beginners to try at first simple effects of lighting, such as can be obtained with the sun on one side of and slightly behind the camera, as brilliant and satisfactory looking negatives are most easily got by this method of lighting. With the sun straight behind the camera a direct front light is thrown upon the landscape, which is usually the very worst form of lighting possible to work with, the resultant pictures being flat, tame, and spotty. Occasionally with subjects which possess great contrasts of light and shade in themselves even a front light may be utilised.

In photographing a wooded landscape, the sun almost immediately in front of the camera and just kept from shining on the lens by a sky-shade, gives, perhaps, the greatest chance of obtaining artistic effect to the photographer who has thorough mastery over manipulative detail, as nature seen right under the sun reveals many beauties otherwise hidden. Under the sun the the shadows are broad and massive, and the heavy summer foliage seems surrounded by a halo of light caused by the reflections from the upper leaves, which glisten and sparkle in the glad sunshine like numberless jewels. In attempting to obtain effects of this kind every possible precaution must be taken to prevent the evil known to photographers as "halation." Fine effects may be often got on days when there is no direct sunshine. A weak, diffused light suits best heavy masses of foliage and deep wooded glens, such as those in which most of our Northumbrian "linns" are situated. While the attention of the photographer is directed to the landscape, atmospheric effects should not be neglected; and an opportunity of taking a fine sky should never be lost, as he who does not make his skies a material part of his picture neglects to avail himself of one of his greatest aids. In the works of all the great landscape painters the skies seem to sympathise with and form part of their subject. The practice, so common with photographers not long ago, of treating the sky as a white sheet thrown behind their landscape is now fast becoming obsolete, and in almost all exhibition pictures, and in many procurable in the shops of photograph dealers, we find natural skies, either produced in the negative by the use of a sky-shade during exposure, or by the more troublesome but more effective way of printing-in a sky from a separate negative taken specially for that purpose.

Having surmounted technical difficulties the amateur will find it to his advantage in every way to turn his attention to some special and definite purpose. To attain excellence in a special line is better than to be content with mediocrity in many, and it is by steady, earnest effort in one direction that the best results are most easily accomplished.

Let me conclude with a word of warning to the beginner. Do not attempt too much at first. It is necessary to creep before walking. I have known a man who could not develope a dry plate properly, and who certainly did not know a good one from a bad one, commence to make his own gelatine plates, giving as his reason that he wished everything connected with the photograph to be his own handiwork. Carrying out his principle he might have started a glass manufactory and a paper mill. To such a man there comes in photography a quick and stern Nemesis. Frequently it comes, after a tour with the camera amid beautiful and enchanting scenery, when in the silence and lurid red light of his developing-chamber he attempts to bring out the images of beauty latent on his plates. One after another is plunged into the developing solution; but instead of the expected pictures there results only fog! fog!—hopeless and universal fog! In his despair he feels photography is a sham and civilisation a failure; and in the extremity of his anguish perhaps he is tempted to utter the big, big D. We may all take warning by the fate of the ambitious youth of heathen mythology, Phæton, who essayed to drive the horses of the sun; and we must remember that the horses of the sun god, whom we photographers so ardently worship, will not be driven, but must be gently led.

RECENT PATENTS.

PATENTS APPLIED FOR.

No. 6,242.—"Obtaining Photographic Images on Porcelain and Enamelled or Glazed Surfaces." J. Wetter; communicated by J. A. Burell. —*Dated April* 10, 1884.

No. 6,323.—"Frames for Holding Photographs and Other Pictures." H. H. Hund; communicated by A. Brüning.—*Dated April* 12, 1884.

NOTICE TO PROCEED.

No. 5,681.—"Improvements in and Relating to Colour-Printing, also Partly Applicable for Producing Coloured Photographs and for Similar Purposes." W. R. Lake; communication from A. Bisson, Paris.—*Dated December* 8, 1883.

PATENT SEALED, April 9, 1884.

No. 712. — "Improved Apparatus for Washing Photographs." F. Hazeldine.—*Dated January* 4, 1884.

Notice.—In the official journal of the Patent Office of the 11th instant, we find a notice of application for the amendment of the specification of George Duncan Macdougald, of Dundee, No. 416, dated January 2, 1884. This specification was published on page 155 of The British Journal of Photography. The proposed amendment will not greatly interest our readers, and, therefore, we refrain from giving the details.

IMPROVEMENTS IN ASTRAGALS OR GLAZING BARS FOR HOLDING AND SECURING GLASS FOR ROOF-LIGHTS AND WINDOWS.

Although this is not a photographic patent, it is believed that it will possess interest to every photographer who has a glass-roofed studio, seeing that it embraces a new method of attaching the glass to the astragals. The invention is by John Fraser, of Wellgate Works, Arbroath, Scotland, and the specification is as follows:—

My said invention has for its object the constructing of astragals or glazing bars in an improved and extremely simple and economical manner. And my invention consists in a new and improved mode of combining strips of thin lead with wooden astragals or bars, the lead strips being used in a manner which is now well known and commonly practised for holding and closing the glass by being folded down on the glass when placed in position. In carrying out my invention a saw cut or deep groove is formed along the top of the astragal or bar, and a pair of lead strips or one doubled strip is inserted in the groove, with the outer edges of the lead projecting sufficiently for being folded down upon the glass. The lead is secured in the groove by transverse nails, sprigs, or pins. A single lead strip may be used in some cases.

And in order that my said invention, and the manner of performing the same, may be properly understood I hereunto append a sheet of explanatory drawings to be hereinafter referred to and representing examples of my improved astragals or glazing bars.

Fig. 1 is a transverse section of a simple modification of the improved astragal, which consists of a bar, 5, of wood having formed along the middle of its top a deep narrow groove for the reception of a pair of strips, 6, of thin sheet lead. After being inserted the lead strips, 6, are fixed by

FIG. 1.

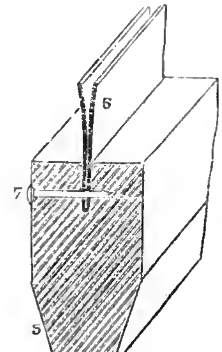


FIG. 2.

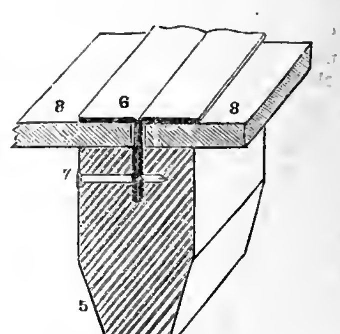

nails, 7, driven in transversely at suitable intervals along the bar. In *fig.* 1 the lead strips, 6, are shown as they are before the glass is placed in position. *Fig.* 2 is a section of the same form of astragal as that shown in *fig.* 1, but with the glass, 8, in position and the lead strips, 6, turned down upon it.

The wooden astragal or bar, 5, may be made of various forms or sections, and, if desired, it may have grooves or gutters, 9, formed along its sides as shown in *fig.* 3, for leading off moisture or water; or such grooves or gutters, 9, may be formed so as to be covered by the glass as shown in *fig.* 4, or as shown in *fig.* 5. *Fig.* 5 also shows a mode of using a single lead strip for securing the adjacent edges of two pieces of glass. This single lead strip is cut from its top edge down to the level of the top of the glass at intervals, and the parts between the cuts are bended down upon the glass alternately to opposite sides.

Instead of reproducing all the figures given as illustrations of the specifications, we confine ourselves to *figs.* 1 and 2, as from them may be deduced all the others. The special claim is—

The fixing of lead strips to astragals or glazing bars by inserting them in grooves formed in the tops of the bars and by driving nails, or the like transversely into the bars and through the lead strips substantially as and for the purposes hereinbefore described.

PHOTOGRAPHIC COPYRIGHT IN THE UNITED STATES.

In this case the Supreme Court of the United States, acting as a Court of Appeal, had before them a copyright case. As it involves the portrait of an Englishman more or less well known, Oscar Wilde, it is believed that every reader interested in the law of copyright in other countries will feel specially interested in this case. The story, as told by Mr. Justice Miller, when delivering the opinion of the court, is substantially as follows:—

The suit (he says) was commenced by an action at law, in which Sarony (photographer, New York) was plaintiff and the Lithographic Company was defendant, the plaintiff charging the defendant with violating his copyright in regard to a photograph, the title of which is "Oscar Wilde, No. 18." A jury being waived, the court made a finding of facts on which a judgment in favour of the plaintiff was rendered for the sum of \$600 for the plates and 85,000 copies sold and exposed to sale, and \$10 for copies found in his possession, as penalties under section 4,965 of the Revised Statutes.

Among the finding of facts made by the court the following presents the principal question raised by the assignment of errors in the case:—

"That the plaintiff, about the month of January, 1882, under an agreement with Oscar Wilde, became and was the author, inventor, designer, and proprietor of the photograph in suit, the title of which is 'Oscar Wilde, No. 18,' being the number used to designate this particular photograph and of the negative thereof; that the same is a useful, new, harmonious, characteristic, and graceful picture, and that said plaintiff made the same at his place of business in said City of New York, and within the United States, entirely from his own original mental conception, to which he gave visible form by posing the said Oscar Wilde in front of the camera, selecting and arranging the costume, draperies, and other various accessories, in said photograph, arranging the subject so as to present graceful outlines, arranging and disposing the light and shade, suggesting and evoking the desired expression, and from such disposition, arrangement, or representation, made entirely by the plaintiff, he produced the picture in suit, Exhibit A, April 14, 1882, and that the terms 'author,' 'inventor,' and 'designer,' as used in the art of photography and in the complaint, mean the person who so produced the photograph."

Other findings leave no doubt that plaintiff had taken all the steps required by the Act of Congress to obtain copyright of this photograph, and section 4952 names photographs among other things for which the author, inventor, or designer may obtain copyright, which is to secure him the sole privilege of reprinting, publishing, copying, and vending the same. That defendant is liable under that section and section 4965 there can be no question, if those sections are valid as they relate to photography.

Accordingly, the two assignments of error in this court by plaintiff in error are:—

1. That the court below decided that Congress had and has the constitutional right to protect photographs and negatives thereof by copyright.

The second assignment related to the sufficiency of the words "Copyright, 1882, by N. Sarony," in the photographs, as a notice of the copyright of Napoleon Sarony under the Act of Congress on that subject.

With regard to this latter question it is enough to say that the object of the statute is to give notice of the copyright to the public, by placing upon each copy, in some visible shape, the name of the author, the existence of the claim of exclusive right, and the date at which this right was obtained.

This notice is sufficiently given by the words "Copyright, 1882, by N. Sarony," found on each copy of the photograph.

The constitutional question is not free from difficulty.

The eighth section of the first article of the Constitution is the great repository of the powers of Congress, and by the eighth clause of that section Congress is authorised:—

"To promote the progress of science and useful arts, by securing, for limited times, to authors and inventors the exclusive right to their respective writings and discoveries."

The argument here is—that a photograph is not a writing nor the production of an author. Under the acts of Congress designed to give effect to this section the persons who are to be benefited are divided into two classes—authors and inventors. The monopoly which is granted to the former is called a copyright; that given to the latter letters patent, or, in the familiar language of the present day, *patent right*.

We have, then, copyright and patent right, and it is the first of these under which plaintiff asserts a claim for relief.

It is insisted in argument that a photograph, being a reproduction on paper of the exact features of some natural object or of some person, is not a writing of which the producer is the author.

Section 4952 of the Revised Statutes places photographs in the same class of things which may be copyrighted with "books, maps, charts, dramatic or musical compositions, engravings, cuts, prints, paintings, drawings, statues, statuary, and models or designs intended to be perfected as works of the fine arts." "According to the practice of legislation in England and America (says Judge Bouvier, 2 *Law Dictionary*, 363), the copyright is confined to the exclusive right secured to the author or proprietor of a writing or drawing which may be multiplied by the arts of printing in any of its branches."

The first Congress of the United States, sitting immediately after the formation of the Constitution, enacted that the "author or authors of any map, chart, book or books, being a citizen or resident of the United States, shall have the sole right and liberty of printing, reprinting, publishing and vending the same for the period of fourteen years from the recording of the title thereof in the clerk's office, as afterwards directed."

This statute not only makes maps and charts subjects of copyright, but mentions them before books in the order of designation. The second section of an act to amend this Act, approved April 29, 1802, enacts that from the first day of January thereafter, he who shall invent and design, engrave, etch, or work, or from his own works shall cause to be designed and engraved, etched, or worked, any historical or other print or prints shall have the same exclusive right for the term of fourteen years from recording the title thereof as prescribed by law.

By the first section of the Act of February 3, 1831, entitled "an Act to amend the several acts respecting copyright," musical composition and cuts, in connection with prints and engravings, are added, and the period of protection is extended to twenty-eight years. The caption or title of this Act uses the word copyright for the first time in the legislation of Congress.

The construction placed upon the Constitution by the first Act of 1790, and the Act of 1802, by the men who were contemporary with its formation, many of whom were members of the convention which framed it, is of itself entitled to very great weight, and, when it is remembered that the rights thus established have not been disputed during a period of nearly a century, it is almost conclusive.

Unless, therefore, photographs can be distinguished in the classification on this point from the maps, charts, designs, engravings, etchings, cuts, and other prints, it is difficult to see why Congress cannot make them the subject of copyright as well as the others.

These statutes certainly answer the objection that books only, or writing in the limited sense of a book and its author, are within the constitutional provision. Both these words are susceptible of a more enlarged definition than this. An author in that sense is "he to whom anything owes its origin—originator, maker; one who completes a work of science or literature." So, also, no one would now claim that the word "writing" in this clause of the Constitution, though the only word used as to subjects in regard to which authors are to be secured, is limited to the actual script of the author, and excludes books and all other printed matter. By writings in that clause is meant the literary productions of those authors, and Congress very properly has declared these to include all forms of writing, printing, engraving, etching, &c., by which the ideas in the mind of the author are given visible expression. The only reason why photographs were not included in the extended list in the Act of 1802 is probably that they did not exist, as photography as an art was then unknown, and the scientific principle on which it rests and the chemicals and machinery by which it is operated have all been discovered long since that statute was enacted.

Nor is it to be supposed that the framers of the Constitution did not understand the nature of copyright and the objects to which it was commonly applied, for copyright, as the exclusive right of a man to the production of his own genius or intellect, existed in England at that time, and the contest in the English courts, finally decided by a very close vote in the House of Lords, whether the statute of 8 Anne, chap. 19, which authorised copyright for a limited time, was a restraint to that extent on the common law or not, was then recent. It had attracted much attention, as the judgment of the King's Bench, delivered by Lord Mansfield, holding it was not such a restraint, in Millar *v.* Taylor, 4 Burrows, 2,303, decided in 1769, was overruled on appeal in the House of Lords in 1774. Ibid, 2,408. In this and other cases the whole question of the exclusive right to literary and intellectual productions had been freely discussed.

We entertain no doubt that the Constitution is broad enough to cover an act authorising copyright of photographs, so far as they are representatives of original intellectual conceptions of the author.

But it is said that an engraving, a painting, a print, does embody the intellectual conception of its author, in which there is novelty, invention, originality, and therefore comes within the purpose of the Constitution in securing its exclusive use or sale to its author; while a photograph is the mere mechanical reproduction of the physical features or outlines of some object, animate or inanimate, and involves no originality of thought or any novelty in the intellectual operation connected with its visible reproduction in shape of a picture. That while the effect of light on the prepared plate may have been a discovery in the production of these pictures, and patents could properly be obtained for the combination of the chemicals, for their application to the paper or other surface, for all the machinery by which the light reflected from the object was thrown on the prepared plate, and for all the improvements in this machinery and in the materials, the remainder of the process is merely mechanical, with no place for novelty, invention, or originality. It is simply the manual operation, by the use of these instruments and preparations, of transferring to the plate the visible representation of some existing object, the accuracy of this representation being its highest merit.

This may be true in regard to the ordinary production of a photograph, and that in such case a copyright is no protection. On the question as thus stated we decide nothing.

In regard, however, to the kindred subject of patents for invention, they cannot by law be issued to the inventor until the novelty, the utility, and the actual discovery or invention by the claimant have been established by proof before the Commissioner of Patents; and when he has secured such a patent, and undertakes to obtain redress for a violation of his right in a court of law, the question of invention, of novelty, of originality, is always open to examination. Our copyright system has no such provision for previous examination by a proper tribunal as to the originality of the book, map, or other matter offered for copyright. A deposit of two copies of the article or work with the Librarian of Congress, with the name of the author and its title-page, is all that is necessary to secure a copyright. It is, therefore, much more important that, when the supposed author sues for a violation of his copyright, the existence of those facts of originality, of intellectual production, of thought and conception on the part of the author should be proved than in the case of a patent right.

In the case before us we think this has been done.

The third finding of facts says, in regard to the photograph in question, that it is a "useful, new, harmonious, characteristic, and graceful picture, and that plaintiff made the same * * * entirely from his own original mental conception, to which he gave visible form by posing the said Oscar Wilde in front of the camera, selecting and arranging the costume, draperies, and other various accessories in said photograph, arranging the subject so as to present graceful outlines, arranging and disposing the light and shade, suggesting and evoking the desired expression, and from such disposition, arrangement or representation, made entirely by plaintiff, he produced the picture in suit."

These findings, we think, show this photograph to be an original work of art, the product of plaintiff's intellectual invention, of which plaintiff is the author, and of a class of inventions for which the Constitution intended that Congress should secure to him the exclusive right to use, publish, and sell, as it has done by section 4952 of the Revised Statutes.

The question here presented is one of first impression under our Constitution, but an instructive case of the same class is that of Nottage *v.* Jackson, 11 Queen's Bench Division, 627, decided in that court on appeal, August, 1883.

After referring to the opinions of Brett, M.R., and Lord Justice Cotton, relative to the individual who is entitled to be considered the real author of a photograph (see page 466 of our volume for last year), he continued:—

These views of the nature of authorship and originality, intellectual creation and right to protection, confirm what we have aleady said.

The judgment of the Circuit Court is accordingly affirmed.

Our Editorial Table.

A Popular Treatise of Modern Photography.

Glasgow: George Mason & Co.

We have reason to complain, in the first instance, of a rather misleading announcement which appears on the cover of this book. It is stated to be "by George Dawson, M.A., formerly Lecturer on Photography, King's College, and Editor British Journal of Photography"—presumably *present* editor. Mr. Dawson was for a time, eighteen or nineteen years ago, *one* of the editors of this Journal; but it is scarcely just to trade on a long-broken connection as he is now doing. Of course, all who are acquainted with Mr. Dawson will be under no misapprehension in the matter; but we think it is only right that we should make this explanation on our own behalf.

The book itself is written for beginners, and contains a good deal of information—original and reprint—that will be found useful by those who have not an intimate back-knowledge in photographic matters. There are some inaccuracies, which are unavoidable in the first edition of any work of this description; but, on the whole, the information is sound.

The University Boat Race. By Wratten and Wainwright.

Messrs. Wratten and Wainwright have this year repeated their feat of four or five years ago, in securing a number of photographs of the annual meeting of the representatives of the two universities at Putney. As is usually the case on "boat-race day," the weather was anything but favourable for photographic purposes—for instantaneous work especially; nevertheless, Mr. Wratten has succeeded in obtaining, during the brief time at his command, about a dozen excellent representations of the race and its attendant incidents. Four of these are published, namely, No. 1, *Clearing the Course;* No. 2, *The Race;* No. 3, *Steamers Following;* and No. 4, *After the Race.* In all of these the various craft are depicted with singular clearness, while the smoke of the accompanying steamers gives a bright and lively appearance to the scene, though there is far less life on the river than we are accustomed to on the occasion of the boat race. These pictures will form an interesting reminiscence of the first victory of Cambridge after a long spell of ill success.

The Obsequies of the Late Duke of Albany.

By G. P. Cartland, Windsor.

These pictures, sent by Mr. Cartland, represent the reception of the late Duke's remains by Her Majesty at Windsor. The first picture shows the reception at the station yard; the second, the gun carriage bearing the remains, and attended by the sorrowing relatives of the deceased; the third picture represents the Guards' band following; and the last, Her Majesty's carriage, drawn by six magnificent white horses. The exposures given were about the one-sixth of a second, the plates employed being, we are informed, Messrs. Wratten and Wainwright's "drop shutter."

Meetings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 10th instant, the chair was taken by Mr. A. Mackie.

Mr. W. E. Debenham said it had been contended at the previous meeting that it was not practicable to precipitate bromide of silver by the Abney process, in a reasonable time, from a solution which should contain as much as (say) one-eighth of a grain to the ounce of gelatine. To prove that it was quite practicable he had, therefore, prepared an emulsion that morning, and then showed some dry films and a negative taken upon a plate coated with it. He also prepared a similar emulsion in the presence of the members, using gelatine one grain, bromide of ammonium twenty-three grains, nitrate of silver thirty grains, and one-tenth of a minim of hydrochloric acid to the ounce. The important point was to let the gelatine solution get cold before adding the silver. If it were hot the silver would emulsify instead of precipitate. After settling down, the supernatant liquid was poured off, and the precipitate emulsified in a solution of gelatine for an hour, at about 120° to 100° Fahr. The emulsion was very slow, but of good quality. The process was convenient when speed was of no consequence, and plates were wanted quickly; as from weighing out the chemicals to coating the plate had only occupied an hour and a-half. A few plates were distributed to those members desirous of trying them.

Mr. A. L. Henderson showed a lantern, consisting of a box with a small paraffine lamp, and furnished with two plates for modifying the light, coated with phosphorescent paint. There were also grooves to admit in addition plates of glass coated with aurine. He found that one plate of aurine and two of the phosphorescent paint gave a safe light for dark-room use. He remarked that the phosphorescent plate next the light was acted upon so as to give out light, whilst the second, shielded by the first, left for any time, did not become phosphorescent, as the first plate seemed to have absorbed all the rays capable of exciting phosphorescence; and as these rays were the same that acted upon the bromide of silver, he thought that the use of these phosphorescent plates as mediums for passing light for photographers' use should be advantageous.

Mr. Debenham said that it would be advantageous to make competitive experiments with plates coated with material of a similar colour to the phosphorescent tablets and of the same intensity.

Mr. Henderson replied that it was difficult to get plates coated to exactly the thickness required.

Mr. Debenham suggested using the colour in the form of an emulsion, and coating several plates to different thicknesses. One of these might, when dry, be selected of the desired thickness.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The sixth meeting of this session was held in 5, St. Andrew-square, on Wednesday evening, the 2nd instant,—Mr. Wm. Neilson, President, in the chair.

The minutes being passed, the following gentlemen were unanimously elected ordinary members:—Messrs. Archibald Brown, John M'Laren, J. Keith Chisholm, David Munro, and Thomas Young.

Mr. Craig Christie moved that the Secretary be instructed to insert in the minutes expression of the sincere regret of the Society at the death of His Royal Highness the Duke of Albany, and that he prepare addresses of condolence to Her Majesty and the Duchess of Albany, to be signed in the name of the Society by the President, Vice-Presidents, and Secretary. This was passed without dissent.

Mr. Craig Christie moved that the following be added to the rules of the Society:—"That the Secretary shall call Council Meetings after consultation with the President, and that he shall give three days' notice to members."

The Secretary said that he had no objection to the proposal. It, however, occasionally happened that some matter of importance cropped up which necessitated prompt action, and when such was the case it might be greatly to the disadvantage of the Society if a delay of four or five days were made obligatory. He suggested that as the Council were about to revise the rules this matter might be referred to the Council. This was agreed to. He (the Secretary) then intimated that he had been favoured with two important papers by the Rev. T. F. Hardwich and Mr. Lewis Wright respectively, and proposed that the programme be departed from in order that these papers might receive the earliest publicity. Mr. G. G. Mitchell had courteously acceded to this, and proposed reading his paper at the next meeting, subject to the will of the meeting.

The proposal having been passed by acclamation, a paper by Mr. Hardwich, entitled *Notes on the Lime Light,* was read by the Secretary, and immediately after notes on the same paper by Mr. Lewis Wright. [See pp. 230 and 233, *ante.*]

Mr. J. M. Turnbull said he had listened with much pleasure to the able paper that had just been read and Mr. Wright's remarks thereon. Mr. Hardwich was acknowledged to be an able and careful experimenter, and members were bound to listen with attention and receive with respect any conclusions to which he might come. With one or two exceptions he agreed entirely with everything that Mr. Hardwich had said in his paper. He thought that the proper angle for the burning gases to strike the lime cylinder should be the greatest that could be given without giving a shadow on the screen—that is, as near a right angle as possible. He agreed with Mr. Hardwich that "light for all ordinary purposes could be got with three-quarter to one hundredweight on each bag;" but where the very best light is wanted to fill a twenty-feet screen he believed in having plenty of pressure. Square weights ought always to be used, or, still better, a long flat-sided weight cast for the purpose, in shape like a piece of pig metal. With regard to the ether generator: he had used it many times with convenience to himself, and believed it was quite capable of giving a light equal to the mixed gases. He thought it quite safe in competent hands, but it should not be trusted in the hands of those who were beginners, or who had only a slight knowledge of what they were doing. In making experiments with the generator packed in ice, Mr. Hardwich did not seem to be aware that all properly-made ether generators were jacketed or encased in a thick coating of some non-conductor of heat, such as cork raspings or sawdust, and consequently not easily affected by cold, or by a little heat such as that of a crowded room. With regard to the Chadderton accident: he quite agreed with the opinions of Mr. Hardwich, Mr. Wright, and the published opinion of Mr. Broughton, that the cause of the explosion was that there was ether in the bag. The fact of the generator being on the table and the gas bag on the floor was sufficient in itself to account for it. They could not have been placed in a more favourable position for the ether to syphon back on the slightest back-pressure arising. Such seems to have arisen from the internal pressure in the generator itself before even the lantern was lighted. He thought Mr. Wright's suggestion to open the hydrogen tap of the generator first in order to relieve any pressure a most valuable one. He did not think Mr. Wright's first objection to ether, namely—want of saturation—a serious one, as he had proved to his own satisfaction that either air or oxygen could be very easily saturated with ether to make them burn freely; but the second objection (that of back-pressure) was one that would require to be seriously met and remedied, either by the construction of a generator that could be blown back without sending the ether back through the tubes or by interposing some thoroughly tried safety contrivance. He had very little faith in back-pressure valves, &c., and the newly-suggested pumice chambers would require to be thoroughly tested before they could be said to be safe.

Mr. W. Hume remarked that the subject was a very important one, and it was a very grave matter to have even the faintest risk of loss of life at lime-light exhibitions. It was, therefore, well to seek by full discussion to eliminate, as far as possible, all the errors of manipulation which might lead to danger. With regard to the preparation of the oxygen: he did not find it necessary to weigh the ingredients; but, when making the gas himself, he simply blackened the chlorate with the manganese dioxide. When once the flow of gas begins the heat should be kept low, for a kind of fusee action goes on in the mixture till all the oxygen comes off regularly if a moderate heat be kept up below the retort. It is of the greatest importance that the tube leading from the retort be ranged out with a stout spiral wire each time the gas is made; for so much solid matter is carried over that it would ultimately choke the pipe if neglected after several makings, and to this cause he attributed some of the accidents that had happened. For those who suspect black materials like manganese dioxide, and do not feel sure of the tests for it, he mentioned that red oxide of iron would suit quite as well; indeed it was much preferred in some chemical laboratories, as giving the gas more free from chlorous compounds. Common sea-sand would also help to give a steady flow of oxygen when mixed with the potass chlorate. He had used the mixing burner he exhibited very frequently for the past five or six years with oxygen and coal-gas in separate bags under one-hundredweight pressure each, without any approach to a casualty; indeed, he considered it the safest arrangement that could be used. The mixing chamber in this burner has no packing whatever. It was not desirable or safe that the weights should fall off the bags; but the last time he gave an exhibition in that room one of the weights fell off the oxygen bag without anything going wrong except the diminution of light, and all went right when his assistant replaced the weight. On former occasions, too, while the light was burning he had lifted weights off and put them on again without any accident or even a snap. Indeed he could not see how an accident could happen with that arrangement without gross carelessness.

Mr. G. A. Wilson said, with reference to the pumice safety-chamber, his objection to it was that, after being repeatedly used or knocked about, some of it was apt to get pulverised and blown into the nozzle of the burner and so choke it up. The only safety-chamber he used was a common piece of cane inserted in the tubing near the burner. Through that no light would pass no matter what the composition of gases might be, and no dust would pass from it into the burner. The diameter and length would depend upon the pressure available or necessary. He had found, with one-hundredweight on the bags, a piece of cane half-an-inch in diameter and one inch or one and a-half inch long, thoroughly efficient. His reason for speaking so confidently of this safety-chamber was that some years ago, before ether was spoken of as a substitute for hydrogen, he had an idea that it might be used, and, therefore, tried several experiments with it. In one of those experiments he fixed a piece of cane firmly in the outlet of the ether generator, with another safety-valve nearer the lantern, and lighted the burner. This gave a splendid light for a short time, but the light suddenly disappeared, travelled along six yards of tubing, sent his first valve to pieces, and burned with great force at the cane, but did not pass through it into the ether generator. After considering a moment (for the noise was very great), he turned off the oxygen tap at the bag, and all was safe. If the flame could pass in one moment along six yards of tubing and stop at the cane, it appeared to him to be the simplest, cheapest, and most reliable safety-chamber at present known. If a piece of cane such as he described were attached to each burner he had not found it possible that an accident could occur, no matter what suction took place by the weights falling off, or in whatsoever proportion the gases were mixed, because they would not explode without a light, and the light was stopped at the cane. With reference to the ethoxo lime-light: he considered it safe so long as it was kept burning sufficiently to make the lime incandescent; but the moment it was turned down with the tap for the purpose of dissolving with a double lantern it became dangerous. He thought the danger due to the dissolving tap beginning at a considerable distance from the ether generator, and the intervening tube became filled with oxygen gas saturated with ether; and, as the little escaping, or rather burning, at the nozzle was not issuing at high pressure, the flame rushed back as soon as the dissolving tap was turned on. Nor is an explanation far to seek, for the ether vapour being heavier than the oxygen gas, some of it has a tendency to regain its original liquid form, and separates from the oxygen, falling back and down the tubing into the generator, leaving behind a decidedly explosive mixture which when liberated at the tap explodes; and it is just a possible thing, without the cane safety chamber, the flame may travel back to the ether generator. Some lanternists held that it was not possible for the flame to travel along tubing; but he maintained that such was not only possible but certain when using the mixed burner, if the weights should fall off the hydrogen bag, causing a suction of oxygen gas into the hydrogen bag. The oxygen gas being such a powerful supporter of combustion would keep the flame burning inside the tubing until it reached the hydrogen bag, and that burning caused a vacuum in the tubing so great that an ample supply of oxygen would be drawn in to form an explosive mixture, so that it was not only the falling off of the weights that caused the suction, but the combustion as well. The whole gas in the bag would then catch fire and explode, just as an ordinary gasometer would do if a light were applied. It was an undoubted fact that bags sometimes caught fire when the weights fell off, and that, he believed, might account for it. With reference to the lantern microscope: he had also been giving his attention to it, and had succeeded in showing a flea (the object, not the disc), six to twelve feet in size, clear and distinct on the screen, by using a specially-constructed lens of wide aperture and high power.

Hearty votes of thanks were accorded to Mr. Hardwich and Mr. Lewis Wright for their valuable papers.

Mr. Annan moved that it be remitted to the Council of the Society to petition, either by letter or deputation, the Convener of the Committee of the Parks and Gardens to remove the restrictions as to taking photographic views in Princes-street Gardens, also the Surveyor for Scotland of H.M.'s Public Buildings and Parks to remove similar restrictions against photographing in the Queen's Park.

Mr. William Hume, as an amateur, seconded the motion.

Several members gave their experience as to having been stopped by the park rangers, while others stated they had not been interfered with. It was considered a great hardship that amateurs and others visiting the city should be debarred from taking photographs where the general public were allowed free access. To such the loss of time in applying for the requisite permission meant the loss of their only opportunity under favourable circumstances. Ultimately an amendment by Mr. James Crighton was passed, empowering the Secretary and President to draw up a letter of appeal, or visit as a deputation, the Town Council for the removal of the restrictions on photographing in Princes-street Gardens.

Circulars concerning the Northampton Museum International Photographic Exhibition were distributed, and a vote of thanks to the Chairman terminated the proceedings.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of this Association was held in the Patents' Room of the Literary and Philosophical Society's Institute, on Wednesday the 9th instant,—Colonel Sheppee, President, in the chair.

The minutes having been confirmed, Mr. W. C. Fletcher was nominated for membership, and Mr. J. H. Inness, F. W. Morgan, J. Russell, and A. Ross were duly elected members.

A report was received from the Council with reference to the exhibition and to outdoor meetings. Some discussion followed, but finally it was adopted unanimously.

The report contained recommendations from the Council as follows:—That no open competition be held this year. That a private exhibition of members' work be held in the autumn, at which a print be selected for exhibition to members, the print selected not to be smaller than half-plate, nor larger than 10 × 8. The members to be the judges. Proposed outdoor meetings:—June, first Wednesday—Haward and Langley: leader, Mr. J. P. Gibson.—July, first Wednesday—Dilston and Devilswater: leader, Mr. J. W. Robinson, Jun.—July, third Saturday afternoon—Dilston and Devilswater: leader, Mr. Goold.—August, first Wednesday—Bywell: leader, Mr. Dodds.—August, third Saturday afternoon—Bywell: leader, Mr. Goold.—September, first Wednesday—Alnwick: leader, Mr. Auty.

The following offers, by gentlemen, members of the Association, had been accepted with thanks:—Mr. George Borrow: A silver medal for the best set of three pictures taken by a member at the Society's outdoor meetings this year.—Mr. J. P. Gibson: A prize for the two best pictures taken at the Society's outdoor meetings this year, the successful competitor not to have previously received a medal or diploma.—Mr. J. A. Maling: A silver medal for the best set of three transparencies taken by a member.

The meeting then adjourned to the adjoining lecture theatre, where

Mr. J. P. Gibson gave an interesting lecture on *Landscape Photography for Amateurs*. [See page 249.] After pointing out the numerous benefits to be derived from the practice by amateurs of outdoor photography, the lecturer showed how, by the rapid advance in the manufacture of photographic appliances, and their consequent cheapening, all necessaries for such recreation might be procured at no great expense. He explained how the technical details of dry plate work could be mastered, and proceeded to show how the many difficulties in the way of amateurs in their attempts at landscape photography were to be overcome. The paper was very well received. At its conclusion,

The President proposed a hearty vote of thanks to the lecturer, which was passed.

Mr. Allison, assisted by the Hon. Secretary, then proceeded with the lantern exhibition. Some beautiful slides were shown and much appreciated. The best thanks of the Association are due to Mr. Allison for his kindness in bringing his lantern, superintending the arrangements therewith, and for the loan of a very fine set of Egyptian slides. Also to Messrs. York and Son, and Messrs. Watson and Sons, of London; Messrs. Mawson, Swan, and Morgan, and Mr. J. F. Maling, of Newcastle; and Mr. J. Bedley Robinson, of Tynemouth, for contributions of slides.

The Hon. Secretary read a communication he had received from the Rev. T. F. Hardwich:—

"*Shotton Vicarage, April* 7, 1884.

"Dear Sir,—I am sorry that I shall not be able to attend the meeting of your Society on Wednesday, the 9th inst., and especially so as I see there is to be a lantern demonstration at the close. The lime light is just now attracting an unusual amount of attention in consequence of the jury at the Chadderton explosion inquiry having advised that restrictions should in future be placed upon its use.

"What we want, in my opinion, is a more general understanding of the causes which lead to these explosions, and then, I think, it would not be difficult to prevent them.

"I speak advisedly when I say that nine out of every ten accidents at lantern exhibitions with the oxyhydrogen or ethoxo lime-light are due to a sudden stoppage of the pressure by which the two gases are forced forwards, and to a return of one of the gases in the wrong direction. This may result either from a weight falling off a bag or from a rent in the india-rubber tubing. It may seem at first that the only effect of a rent in the tubing would be to allow a free escape of the particular gas passing through it; but, if you consider for a moment, you will see that it would also allow a return current of the other gas, so that the two gases would mix at the rent instead of mixing in the chamber of the jet. Under these circumstances there would probably be an explosion if a naked flame were near at hand.

"A lecturer using the lime light should examine his tubing with the same care that the coal miner examines his ropes; and, if the exhibition is likely to be a crowded one, he should put on a back-pressure valve to secure himself against a return current of gas. Of the two, I lay more stress on the use of back-pressure valves than of safety-tubes; but why should we not employ both, and in that way restore the confidence of the public, now so much shaken?

"If some photographic society were to offer a prize for the valve and tube most free in action and least liable to get out of order the ingenuity of mechanicians would soon supply the want.

"It must be borne in mind that back-pressure valves are intended to stop gas, and not flame; whereas safety-tubes are meant to stop flame, but not gas. By forgetting this distinction we may, perhaps, blame a safety-tube where it did not deserve it. A rent in the india-rubber causes an explosion, and we infer that flame must have travelled backwards through the safety-tube attached to the jet; whereas it was *one of the gases* that passed through the tube and meeting the other gas a little lower down formed an explosive mixture, which became ignited from the light in the lantern or some other source.

"My own experiments, so far, seem to indicate that an effectual safety-tube can be made without any difficulty, when it is protected from suction or forcing by the addition of a suitable valve.

"In my own practice I have seldom used these appliances; but if I be spared to see another winter I shall, when lecturing away from home, employ the blow-through or safety jet, if practicable, and if not shall protect myself as far as I can against all contingencies in the way now suggested. A blow-through of the kind described in the paper which I read last year before the Newcastle Photographic Association is very powerful, and for most purposes as good, or nearly so, as the mixed gases of the ethoxo lime-light. "T. FREDERICK HARDWICH."

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held in the Religious Institution Rooms, on Tuesday, the 8th instant,—Mr. Hugh Reid, President, occupying the chair.

The question-box contained the following:—"Has any member tried the North British dry plates?" Several members testified to their being extremely rapid, and better worked with a shutter.

The following new members were then admitted:—Messrs. H. G. Gillespie, Robt. T. Cochrane, Jas. S. Stewart, Jas. Bell, Chas. S. Mair, Wm. France, and Wm. Reid.

Mr. J. Y. McLELLAN then exhibited and explained Mr. Warnerke's sensitometer. Mr. McLellan, however, did not consider it altogether satisfactory, as from his observations it tended to deteriorate with age. Plates which he found of the same rapidity in practice last year gave the number 20 quite distinctly, this year only gave a little over 14.

Mr. W. GOODWIN suggested that temperature had a great effect on these phosphorescent tablets.

The discussion was continued by Messrs. Lang, Reid, and others.

Of the two plates tested by Mr. McLellan, both out of the same batch, one exhibited the number 14 and the other only 10. The plate exhibiting 14 had previously been treated by the Chairman with Dr. Eder's formula for rendering plates more sensitive, viz., nitrate of silver fifty grains, citric acid fifty grains, water one ounce. The plate was soaked for three minutes in one drachm of this solution to twelve ounces of alcohol. This showed an increase in the sensitiveness in the ratio of three to one, which corresponds with Dr. Eder's results.

Mr. W. C. BERGINS exhibited his novel form of portable tourist camera, and in the course of a few introductory remarks said that a portable tourist camera, which would unite all the qualities of a studio camera, an enlarging camera, and a landscape camera, was as impossible as a horse which would combine all the qualities of a racehorse, a Clydesdale, and a Shetland pony. His aim in designing this camera had been extreme lightness as well as the necessary strength. In showing the camera, which had been made throughout from his own designs and under his own superintendence, Mr. Bergins pointed out that it was a whole-plate, solid camera, made so that the four slides, two fronts, two lenses, and all other necessary apparatus were carried inside. The principal points were extreme lightness, the whole apparatus weighing only eleven and a-half pounds, carrying seven plates, very small bulk; and, although the camera was made solid, it could focus from five to eleven inches by putting the slides nearer or more distant from the front, the exact focus being attained by rack-and-pinion lenses. The tripod was made of bamboo cane going up like a walking-stick, and when a silk cover was drawn over it had the exact appearance of a pretty heavy umbrella.

The members examined and admired Mr. Bergins's camera and tripod, and he kindly answered a great many questions concerning it.

Mr. GOODWIN then read a short lecturette and gave a demonstration of *Photomicrography* [see page 248], taking a couple of very successful plates—one of a flea and the other of a bit of a cigar box.

The members were very much pleased with Mr. Goodwin's deftness of hand and his extremely-clear method of work, and doubtless many will now "go in" for this branch of photography.

The CHAIRMAN showed a camera-finder and view-meter which he had had made at a trifling cost according to the directions in the *Year Book* for 1884.

The members considered both very useful, especially the view-meter.

It was agreed, after a little discussion, that the first outdoor meeting of the season should be held on the first Monday in May, that the place be the Brig' o'Turk and Trossachs, and that members leave by the 6.50 or 9 a.m. trains.

After the usual votes of thanks a very large and successful meeting was adjourned.

LEEDS PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of this Society was held on Thursday, the 3rd inst., in the Library of the Leeds Philosophical Hall,—Mr. J. W. Ramsden, Vice President, occupying the chair.

The following gentlemen were elected members of the Society:—Messrs. Hardy, Hubbersty, Stokoe, and Grimshaw.

Mr. H. Pocklington then read his paper, entitled *Notes on Developers.* [See page 249.]

Mr. WASHINGTON TEASDALE said he had tried, he believed, every kind of commercial plate. The conclusion he came to was that nearly every plate was capable of giving good results, and that good results could be obtained by most of the developing formulæ. The great question was how the developer was applied to the plate.

The CHAIRMAN said that for negatives he had a strong objection to either green or brown tones. He was anxious to obtain a colour that would allow the light to penetrate in such a way that he could be sure of getting on the print all the details that were to be seen in the negative. If it were a question of the colour of lantern slides then it was another thing altogether, and the result obtained depended whether they worked in what he would call the acid or the alkaline lines. He would give two formulæ, both giving good results:—

Pearlash	½ ounce.
Water	1 pint.

Add two grains of pyro. to each ounce.

If the plate were fixed in the ordinary hypo. bath the result would be a brown tone; but if a quarter ounce of pearlash be added to each pint of the fixing bath the result would be a golden-brown. If, now, any of the ordinary clearing solutions were poured over the plate the colour would change to a purple-black, and could be again changed into a golden-brown by immersion in the hypo. The second formula was—

Sulphate of iron	3 ounces.
Water	10 ,,
Tartaric acid	1 drachm.

Mix one part of the above to six parts of saturated solution of oxalate of potash. A plate so developed, if fixed in the ordinary hypo. bath, has a cold tone; but if fixed in the alkaline hypo. bath it has a beautiful purple-brown tone.

Mr. J. W. REFFITT reminded the members of a plan, suggested by Mr. Rogers, of washing the plate well after development, and, if not sufficiently dense, of increasing the density by flowing over it a solution of ammonia and bromide. In his own practice, if a plate did not come up satisfactorily, he found it best to mix up a fresh developer and place the plate in it, when details and vigour would at once appear.

In reply to a question,

The HON. SECRETARY said almost any tone of chocolate-brown could be obtained on a bromide plate by increasing the exposure and developing in a solution of ferrous oxalate with a large excess of citric acid.

Mr. TEASDALE, in reply to another question, said the best way to obtain a good negative from one that was rather weak was to make a transparency in the camera, under-expose, then over-develope, and, if the result were not satisfactory, to repeat the process in making the negative from the transparency.

The CHAIRMAN recommended the use of washing-soda with pyro. for the production of negatives from engravings, &c., and for photolithography.

Mr. W. T. GRIMSHAW exhibited some very pleasing effects of landscapes, &c., printed on ferro-prussiate paper.

The meeting was then adjourned.

BERLIN ASSOCIATION FOR THE CULTIVATION OF PHOTOGRAPHY.

THIS Association met on the 7th March,—Professor H. W. Vogel in the chair. Several additions having been made to the library, it was resolved to publish a complete catalogue of the books in the *Mittheilungen.*

A number of groups of Indians of the tribe called "Los Caribes" (Brazil), taken by an amateur, Carl Möhle, were then shown.

Some American portraits were exhibited, and gave rise to remarks upon the superiority of the American photographic printer over his European rival.

The discussion then passed to the training of the negative operator, and a wish was expressed by several of those present that suitable courses of lectures on chemistry and æsthetics might be inaugurated for them.

Herr QUIDDE remarked that he feared they would be but poorly attended. Many photographers to whom they might be useful lacked the time required to attend them and the money to pay for them, and, he feared, in many cases also the desire to benefit by them, as most young people knew that if they were sufficiently skilful manipulators they might get good situations without the trouble of real study. Very often the masters also would be the better for a little study.

The CHAIRMAN, while agreeing with what Herr Quidde had said, felt very much inclined to institute such a set of lectures, which would probably have to meet in the evenings or on Sundays, and the fee would have to be extremely small. He was aware that a course of lessons on retouching, taught by an academically-trained retoucher, had met with little or no encouragement, but he was willing to sacrifice something in the cause.

Herr OCHS (of Frankfurt-am-Oder) recommended the use of tartaric acid instead of sulphuric acid to acidify the iron developer—in the proportion of four grammes of tartaric acid to 500 c.c. of developer.

Herr JOOP recommended citric acid.

Herr HABERLANDT had tried the citric acid, but found that it made the film cockle. He had also been advised to slightly increase the proportion of sulphuric acid to the developer, but had found less delicacy in the high lights and a general hardness. [Dr. Vogel confirmed this last statement.] He had also once laid a half-dry gelatine negative in alcohol in order to dry it rapidly, and found afterwards that the parts which had still been moist when laid in the alcohol had been strengthened (intensified). The inference was that, for very *slight* intensification of gelatine plates, alcohol might be used. But plates so treated with alcohol must not be placed upright, but left to dry in a horizontal position; otherwise they would be apt to become streaky.

The CHAIRMAN and Herr JOOP had had similar experience with alcohol, but they could not give a sufficient explanation of its intensifying action.

Herr HABERLAND mentioned another peculiar case. A wet collodion plate which had been intensified with mercury had to be weakened with cyanide of potassium, which usually takes place readily enough. In this case, however, instead of being weakened by the cyanide the plate was actually intensified by it.

The CHAIRMAN said that old cyanide of potassium solutions contained a great deal of carbonate of potassium, and that the cyanide of potassium itself disappears by spontaneous decomposition, so that one would naturally expect the action of old solutions to be different from that of freshly-prepared solutions.

Dr. KAYSER showed a roll of sensitive gelatino-bromide film upon a flexible support two metres long. This he had at first tried to use (like Mr. Warnerke) by rolling it up in a dark slide, but latterly he had cut the sensitive film with its flexible support into pieces the size of the glass plate he would otherwise have to use. He also, to keep it flat, pasted these pieces upon cardboard the same size. The side of the dark slide was furnished with a light-tight sleeve, through which the operator inserted his hand in order to remove the exposed film.

A number of portraits, by Riemann, of San Francisco, and of lichtdrucks, by Schober, of Carlsrühe, were shown, after which a discussion on the merits and difficulty of producing burnt-in enamels followed.

The CHAIRMAN made a few remarks *apropos* of electric lighting, and the ignorance of the general public in regarding a thing as necessarily good *because it had been patented.*

The meeting was then adjourned.

Correspondence.

DRY PLATES IN SWITZERLAND.

To the EDITORS.

GENTLEMEN,—Mr. W. H. Harrison writes in the last Journal that only Monckhoven's plates are to be obtained in Switzerland. Allow me to say that my agent, Mr. C. G. Serinzi, 22, Rue de Lausanne, Geneva, keeps the plates manufactured by me in all standard sizes, and from him tourists and others may obtain what they require.

I may state, also, that there is no danger of the plates having been exposed to light, as no customs examination is required in Switzerland.—I am, yours, &c., J. DÉSIRÉ ENGLAND.

London, April 9, 1884.

IS A PHOTOGRAPHER AN ARTIST?

To the EDITORS.

GENTLEMEN,—I have noticed in your Journal some correspondence upon the question whether a photographer is an artist. In a case in our Supreme Court, in which the copyright in photographs was in question, a decision has been rendered, some portions of which may interest your readers.

The view I took in the argument was that each work must be judged upon its own merits, and that while some photographs could properly be classed as works of art, others might not attain to that dignity.

That view, substantially, was taken by the Court, as you will see. I send you a copy of the decision by this mail.—I am, yours, &c.,

32, *Park-place, New York, April* 4, 1884. A. T. GURLITZ.

[An abstract of this decision will be found in another page.—EDS.]

A QUESTION OF PRIORITY.

To the EDITORS.

GENTLEMEN,—I thank Mr. Lang for his letter, which is, so far, confirmatory of the impression I had as to the discovery of the commutability of the light impression on a chromo-gelatine film being an old one; but he has omitted to reply to the question as to *when* Captain Abney first published the discovery.

Will he kindly give the date, and the name of the publication in which it is to be found.—I am, yours, &c., A. COLLIER.

April 14, 1884.

Notes and Queries.

R. W. C. would like some reader to inform him "what metals the most readily transmit heat, and what metals resist heat the most. Also, if there be any composition that will convey water through fire and transmit the heat to it more readily than metal."

L. R. MCLACHLAN inquires:—"Can you advise me of a good process for coating canvas (for the purpose of enlargements) with emulsion? also, if there be any work published describing the method?"——In reply: We are not aware of any work of this nature. Can any reader afford the information?

B. F. writes:—"I am desirous of making a large number of lantern transparencies. Kindly advise which of the many processes now before the public I should adopt."——In reply: Our correspondent should confine himself to wet collodion and the copying camera. Let the collodion be rather thin, and by preference fully ripe, if not somewhat old. Develope with iron and tone with platina, if tones of a neutral character are desired.

"WHAT is the relationship between the gramme and the cubic centimetre? I have been reading formulæ professing to be translations from the French, and things have got a little 'mixed.'—GEORGE J. JOHNSON."——In reply: The cubic centimetre is a measure for fluids, whereas the gramme is a weight for solids. Both, however, amount to nearly the same thing, very much in the same way as our ounces and drachms, which are both weights and measures.

"IN your *Notes and Queries* of last week your correspondent, F. Dugon, attacks me for having 'thrown out inuendoes somewhat unjustifiable.' When one writes for the interest of fellow-labourers, and with the sole view of helping them, it is scarcely wise or gentlemanly for Mr. F. Dugon to throw out 'inuendoes' or to doubt an assertion which he cannot disprove or for one moment contend against. If your correspondent will send you one guinea for the benevolent fund if I prove my statement, I will send you two guineas if I fail. Will Mr. F. Dugon agree to this?—J. BERRYMAN."

FREDERICK W. MUNCEY writes:—"I should esteem it a great favour if you would answer the following, as I experience some considerable difficulty with stops in my lens (rapid rectilinear):—Which is preferable to use—a small stop and give long exposure, or a larger one and short exposure? I find the greatest difficulty in the subject of interiors as regards the stops. Any information on the above will be most gratefully received."——In reply: Always employ the largest stop by which the required degree of definition can be obtained. In the case of interiors it is well to use a much smaller stop than it would be desirable to employ when photographing a landscape or other outdoor scene.

"WILL you tell me how to proceed to chemically clean an article of solid silver with a good deal of *delicate frosted tooling* upon it, so as *not to polish* the tooled work? It has become much tarnished by exposure to the air, and the ordinary plate-cleaning materials do not bring it up *white* and clean, but sink into and leave a smudgy look about the tooled work. I have an idea that soaking it well in a solution of iodine and iodide of potassium first, and then in strong hyposulphite of soda, would restore its whiteness by turning the present oxidation into iodide of silver, and dissolving it. You may know of some better method—possibly of dilute *acids;* but I am afraid of venturing on them without some preparatory instruction.—LUX."——In reply: Articles of silver are "bleached" or frosted by first washing them quite clean, and then heating gently and with care, so as not to melt the solder, afterwards plunging into water to which has been added from twenty to forty per cent. by volume of sulphuric acid. Let "Lux" subject himself to an educational course as follows, previous to attempting his skill upon the special article described:—Place a shilling or a florin upon a ring of stout wire, and hold it over the flame of a spirit lamp until it becomes nearly white—which will be the case before it acquires a red heat—and then throw it into water strongly acidulated with sulphuric acid as described. When he is able by these means to make his coin of a pure matt white, like the new silver dial of a watch or like a disc of clean white paper, which he will do after one or two trials, he may then venture the treatment upon the silver article to which he refers.

Exchange Column.

I will exchange several cases of stuffed birds, in perfect condition, for photographic apparatus or accessories.—Address, H. STONE, Drayton, Taunton.

Wanted, a good portable studio, 15 × 6 feet will do, in exchange for photographic apparatus. See sale column.—Address, GEO. FEAR, photographer, Trowbridge.

I will exchange whole-plate J.S. portrait lens, rack focus, in perfect condition, cost £5 a year ago second-hand, for instantograph, or offers.—Address, E. B., 10, Wellington-street, Gloucester.

I will exchange Stanley's 5 × 4 portrait lens, camera, and stand for Lancaster's quarter-plate instantograph or *Le Méritoire* complete.—Address, J. GRIMSHAW, 16, Dale-street, Haslingden.

Wanted, in exchange for strong tripod stand, 6-inch brass triangle top, an old bellows camera, half-plate square, with or without focussing or dark slide.—Address, J. COLLIS, 5, Despencer-street, Cardiff.

I will exchange a 10 × 8 burnisher, new, plain cloth (woollen), background, and drying-box. Wanted, a half-plate *Le Méritoire* or the instantograph with three or more double dark slides.—Address, C. ARTHUR, Senhouse-street, Maryport.

I will exchange my dark box, on fifty-inch wheels, for Ross's No. 1 portable symmetrical lens or a pocket camera with at least three double dark slides. May be seen any evening after six o'clock.—Address, J. G. D., 30, Lower Robert-street, Plumstead, Kent.

Wanted, a fine 11 × 6 portable landscape camera, by Meagher, two single slides, stereo. arrangement, fine landscape lens, by A. Ross, fifteen-inch focus, rack and pinion, in exchange for a symmetrical or rapid doublet lens, or offers.—Address, H., 16, Berkley-square, London, W.

I will exchange a large quantity of joiners' and cabinet makers' tools, also a 10 × 8 bellows-body camera, with single back, folding tailboard, and rising-front, value £7, for a good 12 × 10 tourist's bellows-body camera, with not less than three double backs.—Address, SEDGWICK, South View, Sedbergh, Yorks.

I will exchange a 10 × 8 glass bath, in case, and glass dipper, also a half-plate glass bath, in case, with ebonite dipper, for a water-tight bath about half-plate. I have also a balustrade and pedestal, a landscape background, a large artificial rock, a quarter-plate camera, tripod stand, and Cassell's *Popular Educator*, in three large volumes, new. Wanted, Lancaster's pocket camera, printing-frames, view lenses, or what offers?—Address, JAMES BREMNER, 1, St. James's-road, Forfar, Scotland.

Wanted, a good 10 × 8 or larger modern tourist's bellows-body camera, with double slides and good wide-angle lens, in exchange for a splendid, large musical box, walnut, beautifully inlaid, with patent winder, &c., barrel sixteen inches long, plays eight operatic airs; also a mahogany sliding-body camera for plates 6½ × 4¾, with three dark slides and a quarter-plate portrait lens, all by Hocking and Co.; a glass bath for plates 10 × 8, with a quantity of silver solution, and a nearly new portable tripod with sliding legs.—Address, THOS. HIRST, Main-street, Sedbergh, Yorks.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

NOTICE.—*Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a* NOM DE PLUME *as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.*

R. JOYNER.—Probably the negative, and not the paper, is at fault. See answer to "G. W. G."

H. W. B.—Several formulæ for negative varnish are given in our current ALMANAC, to which we refer you.

A. A. A.—The proportion of alcohol you have added to the emulsion is much too large. One-third the quantity would have been ample.

R. HAZEL.—The gentleman is still alive and, we believe, in perfect health, though he has long since relinquished the practice of photography.

HY. J. LOCOCK.—From your description of the apparatus we surmise it is intended for measuring the focal length of lenses, such as spectacle eyes.

THOS. WILSON.—The cause of the dull patches on the enamelled prints is due to their having been removed from the glass before the gelatine was thoroughly dry.

A. Z.—Common spectacle lenses will answer the purpose nearly, or quite, as well as more expensive ones. Any working optician will supply the lenses of almost any focus.

J. G.—The law requires that a license should be taken out to use a still for any purpose whatever—even for distilling water. We fear, however, that the law in this respect is frequently infringed, and a penalty incurred.

A. B. X.—The parcels post will carry glass if properly protected, so as not to be likely to cause injury to other parcels or to the officials. The Post-Office will not be responsible for breakage, so you must pack carefully.

W.—You do not say if you wish to make the plates or to purchase them ready prepared. From what you say we imagine the fault in your negatives is due to the development, and not to the preparation of the plates.

MAJOR GUBBINS.—1. The glass referred to is manufactured by Messrs. Chance Brothers.—2. There is no other society that holds its meetings nearer to your new abode than the Bristol and West of England Photographic Society.

OMEGA.—The paper, if it be at all like the sample enclosed, is quite worthless, except to be burnt and added to your residues. It appears to have been kept where some injurious fumes have had access to it, and so caused the bronzed discolouration.

C. W. W.—Very good work can be done by the Pretsch process; but, so far as we are aware, it is not now being worked in this country—at least under the "Pretsch" designation. As a rule, experts who work photo-engraving processes do not publish the details of those they employ.

G. W. G.—Probably the samples of paper you have employed were over-toned. Possibly, however, the negatives may be at fault. You must bear in mind that unless the negative itself be a strong and vigorous one it will be quite impossible to obtain rich purple tones with any paper.

FOGGED AMATEUR.—If you refer to the article by Mr. W. K. Burton in which the table was given you will find the information you require. The terms "twenty times" or "thirty times as sensitive as wet collodion" simply mean nothing in practice. The object of the extra gelatine discs is for use when very prolonged exposures are required.

LOTTIE.—From the charming little pictures enclosed you certainly require no instruction in the selection of your subjects. A little more experience will enable you to overcome your very slight photographic shortcomings. Over-development appears to be the chief fault in the examples forwarded. We shall, indeed, be pleased to receive the promised pictures.

RUSSELL STEELE.—So much has appeared in our columns during the last few months on the subject of light for the dark room that we are somewhat surprised at receiving your query. If you refer to the back numbers you will find all the information you require. We are sorry we cannot assist you further, as you do not say if you intend employing artificial light or daylight.

S. J. STEPHENSON.—The streaks and smears on the "chromotypes" arise from the waxing of the plates. After applying the solution you have not sufficiently polished the plate; hence the "smears." The plate should be polished, so that no trace of wax may be apparent on the surface. If there be, you may rely upon its showing on the finished print. "Flexible support" will give you a very good surface, but not equal to that given by glass.

AMATEUR.—Without being made aware of the actual quantity of chloride of silver in the paper it would be impossible for us to state the theoretical quantity of hyposulphite of soda which would be required to fix each sheet. Practical photographers rarely trouble themselves on this point, as the hyposulphite is so cheap they always employ a very large excess to be on the safe side. A small quantity only of acetate should be added occasionally.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 23rd inst., the subject for discussion will be—*On Lighting in Landscape Photography.*

TRADE CATALOGUE.—From Messrs. W. Watson and Sons, 313, High Holborn, London, we have received a copy of their new *Catalogue of Photographic Lenses, Cameras, and Accessory Apparatus*, new and second-hand. It is very comprehensive, occupying sixty-eight pages.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
April 22	Bolton Club	The Studio, Chancery-lane.
" 23	Bristol Amateur	Studio, Portland-st., Kingsdown.
" 23	Photographic Club	Anderton's Hotel, Fleet-street.
" 24	London and Provincial	Masons' Hall, Basinghall-street.
" 24	Liverpool Amateur	Free Library and Museum.
" 24	Oldham	Hare and Hounds, Yorkshire-st.

METEOROLOGICAL REPORT.

Observations taken at 406, Strand, by J. H. STEWARD, Optician,
For two Weeks ending April 16, 1884.
THESE OBSERVATIONS ARE TAKEN AT 8.30 A.M.

April.	Barometer.	Wind.	Dry Bulb.	Wet Bulb.	Max. Solar Rad.	Max. Shade Temp.	Min. Tem.	Remarks.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1251. Vol. XXXI.—APRIL 25, 1884.

LENSES OF THE PAST, PRESENT, AND FUTURE.

The comprehensive lecturette *On Lenses*, delivered before the London and Provincial Photographic Association, by Mr. W. E. Debenham, and which will be found on another page, evoked a pleasant discussion, in the course of which several matters not generally recognised by the generality of photographers were elicited.

Some, for example, are deterred from forming an intimate practical acquaintance with photographic optics on account of their imperfect knowledge of mathematical science. To these it will be consoling to be informed that there are some professional photographic lens manufacturers who are quite ignorant of mathematics, yet of whose productions the great excellence is universally admitted. As one speaker said, a profound acquaintance with chemical laws is not absolutely necessary in the preparation of sensitive plates possessing even great merit, and so is it as regards mathematical acquirements in the construction of a photographic lens. On the authority of one who took part in the debate, himself a mathematician, we learn that Mr. Leon Warnerke underwent an arduous course of study in mathematics in order to qualify himself for becoming properly acquainted with the nature and working of photographic lenses, only to throw this all aside afterwards in favour of the simpler and better mode of ascertaining their capabilities by screwing them on the camera and witnessing in what manner they behaved when projecting an image on the ground glass.

In the testing of lenses this method is unexceptionable; but where mathematical knowledge is really required is in the working out of new forms or systems of lenses, although it is known that some of these new systems have not been the result of such investigations as are here implied.

The system introduced eleven years ago by the Astronomer-Royal for Scotland, for enabling a picture to be obtained on a flat plate by the full aperture of a portrait lens with such a degree of marginal sharpness as to be susceptible of after-amplification, was explained by still another speaker, who showed, by means of diagrams on the black-board, the path taken by the central and oblique rays after entering the anterior surface of the interceptor, which consists of a large plano-concave lens placed immediately in front of the sensitive plate, with its concave surface next to the lens. It was explained how, by the agency of this intercepting corrector, the oblique or marginal rays, which would otherwise have been brought to a focus at a point far short of the sensitive surface when the centre was sharp, were converted into a condition of parallelism, and in this state brought into closer proximity to the surface of the plate when they were liberated, and allowed to converge to a focus on the sensitive film.

In the course of the discussion an opinion was also hazarded as regards the probable nature of the lens of the future. This, the speaker said, would, he thought, partake of the general character of the dialyte, by which he meant a front lens of positive focus, whether achromatised or not, that would have its aberrations controlled by a back lens of a negative description. The reader acquainted with the history of photographic optics will readily perceive that this principle was identical with one of the two forms of lens calculated by Petzval. Of these one was the portrait combination; the other, after being allowed to remain dormant for many years, eventually emerged as the orthoscopic—mistakenly so named, seeing that it was not orthographic at all, and, from the nature of its construction, could not possibly be so. We may add that no such claim was even advanced on its behalf by the inventor. Since those days, however, the problem has been again considered, especially by Steinheil, who, by taking advantage of the superior qualities of optical glass now procurable, has modified the form of the dialytic lens with certain well-marked advantages.

But even in its original form—or, perhaps, more correctly, with a very slight departure from its original form—this lens possesses features not generally recognised; for the orthoscopic objective was discarded in favour of others before its powers and capabilities were well understood. So potent is the influence of a negative combination upon one of positive character, that by the mere separation of the components to the extent of a quarter of an inch, a difference is produced in the focus of the objective—in some instances exceeding one inch; while such an extent of separation, small though it be (especially in a lens of long focus), materially influences both the definition and flatness of field. Such is the degree of perfection attainable as regards definition that Petzval employed a combination of this form as an object-glass to a telescope. Central definition of such a quality, conjoined with marginal sharpness in fair ratio, are properties which should secure for any combination of this kind the greatest consideration.

With two such antagonistic combinations as a positive and a negative it is possible to effect a compromise of their respective characteristic powers in a more perfect manner than if both were positive, and possessing features, whether for good or for evil, in a similar direction. This method of combining opposite forces has its parallel in chemical manipulation, in which by the judicious admixture of an acid and an alkali, or of any bodies which react upon each other, a third substance will be obtained, either in a state of neutrality or with a more or less marked preponderance of either of the combining substances at the will of the chemist.

In previous articles we have spoken of thickness as an element in the correction of a lens, especially as regards spherical aberration. Perhaps the most notable example of the application of this factor in correction is to be found in the recently-introduced antiplanat of Steinheil, in which the back combination, like that of the original orthoscopic, is negative. But, whereas the individual components of the orthoscopic back were very thin, those of the newer lens are thick in an abnormal degree—in a degree exceeding all others hitherto made, if we correctly estimate some diagrammatic illustrations of the objective in question, with which we must confess personal unacquaintance. This extra thickness of glass is not, however, confined to the lens to which reference has just been made; but is now a peculiarity in several others of entirely different construction, though they in some degree owe their inception to the continental *savant* previously named.

It will be gratifying if the various papers, lectures, or lecturettes on lenses which are now being occasionally brought before some or other of the societies prove the means of inducing photographers to turn their attention, in a more earnest manner than heretofore, to the nature and construction of lenses. Intricate chemical investigations and manipulations are made by the non-professional chemist; what is there to hinder a similar outcome of scientific ingenuity from being brought to bear upon lenses? The pleasure to be derived would far more than compensate for the imaginary trouble, while photography would be the gainer.

A NEW DEVELOPER.

It may surprise some of our readers to learn that the new developer which today we introduce to their notice is only an old friend with a new face—neither more nor less than sulphite of soda. The remarkable properties of this salt—which to those who have given it a fair trial are too pronounced to admit of dispute, and too valuable to allow it to fall into disuse—have yet been so much the subject of discussion, allegation and denial as to its peculiarities having followed one another in a most confusing fashion, that we determined to institute a series of experiments to set dispute, at anyrate upon some of its properties, at rest. Incidentally we discovered, while prosecuting our researches, that sulphite of soda possessed a power, similar to that possessed by ammonia and the fixed alkalies, of developing, when combined with pyrogallol, the image on a gelatine plate.

The course of our experiments showed, in the first place, that sulphite did not produce green fog; in the next, that in all probability it is the reverse of a retarder; and, thirdly, as we say, that when mixed with pyro. it was capable of developing a plate without any other chemical being added. We have made a large number of trials, and have still more in progress, but none of them are calculated to throw any doubt upon the conclusion at which we have arrived. It will suffice for our purpose if we here describe some of the leading experiments we made.

A mixture of nine grains of pyro., eighteen grains of sulphite of soda, and four ounces of water was made, and a plate which had had the same exposure that would have been required for ammoniated pyro. development was placed in it. After a lapse of about ten minutes the lightest portions of the image began to show themselves, and the negative then gradually gained in detail and intensity till, in ninety minutes, a printing negative of first-rate quality was produced, and one which we do not hesitate to say might have been placed in the hands of ninety-nine out of a hundred printers without their observing anything unusual in it.

This was a fact sufficiently remarkable to render further investigation desirable. The first thought that might naturally arise would be regarding the purity of the sample employed. It was "recrystallised sulphate of soda," purchased from a first-class house, and answering every test for ordinary impurities. As this salt, however, is manufactured by the addition of a measured quantity of carbonate of soda to a solution of sulphurous acid neutralised with soda, there was the chance that, though recrystallised, there might in the successive crystallisations have been retained in the crystals sufficient carbonate to act as a developer without any question of sulphite. We carefully tested the sample, and found no reason to suspect the presence of that salt. Litmus paper is no real test, for the sulphite is a salt with an alkaline reaction naturally, so that, however rigidly it may have been purified, it would turn red litmus paper blue; hence the addition of an acid till neutrality to litmus paper was reached would not necessarily show that free alkali was the cause of the acid being "killed."

We, nevertheless, added citric acid to a solution of sulphite till no change was capable of being produced by it upon litmus, and then we ascertained the amount of carbonate of soda required to neutralise this quantity of acid. We arrived at the conclusion that one grain of carbonate represented the fullest neutralising capacity of twelve grains of sulphite.

Possessing these data we mixed a fresh batch of solutions, composed only of carbonate of soda and pyrogallol. Taking six grains of pyro., and one grain of carbonate of soda as representing the utmost alkaline equivalent of the twelve grains of sulphite, we placed in it one half of an exposed plate, and developed it side by side with the other half in the pyro. and sulphite. In an hour's time the latter (which was fully exposed) reached a density almost sufficient for printing purposes, while the sodaic solution in the same time gave a poor, feeble, under-exposed image utterly worthless for any purpose whatever. Solutions were then made with three and with six grains of carbonate to the same quantity of pyro. as before, namely, six grains. The whole plate became covered with fog before any image had time to appear, and at the conclusion of an hour not a trace of one was visible through the fog.

It thus appeared probable that the sulphite, as well as possessing a power of initiating development, might also act like a bromide in preventing fog; and, to test this we exposed fresh plates and developed them as we did the last, with the exception that we added twelve grains of sulphite to each solution, giving the same exposure. The effect of the addition was remarkable. In place of hopeless fog a soft and delicate image was brought out quite free from fog, and showing evident signs of over-exposure.

It is clearly evident from this record of our experiments that sulphite of soda, when joined with pyro., possesses a power of its own—quite irrespective of any free alkali that it may contain—of completing the development of a picture, and we have shown also that it assists, or is assisted by, carbonate of soda to the same end. What its precise function is when associated with ammonia should, in practice, be well known; that point, however, it is not our purpose at present to discuss. We are continuing our experiments with larger proportions of sulphite and other variations, and we shall lay them before our readers if they present, as is most probable, further points of interest.

We may conclude our present remarks by pointing out certain characteristics of the negatives we obtained. Firstly: in none of them (prolonged as was the development) did the sickly, deep yellow "pyro. stain" become visible—a stain which even sulphite does not entirely prevent in a long development. This stain appears to require the presence of ammonia for its production. Secondly: not a trace of green fog was visible, though the plates under experiment could be made to exhibit it under a forced ammonio-pyro. development. Finally: there is every reason to believe from these recorded results that sulphite is the reverse of a retarding agent—a result contrary to the recorded experience (erroneous, as we believe) of many experimentalists.

THE EFFECT OF HEAT ON BICHROMATED GELATINE WHILE IN A FLUID CONDITION.

The interest taken in processes based on the action of light upon gelatine in conjunction with the alkaline bichromates, such as the numerous photo.-relief processes, appears to be constantly increasing. There is no disguising the fact, however, that all processes dependent upon the reaction of light on bichromated gelatine are beset with difficulties to those who are unfamiliar with those reactions. Perhaps, on the present occasion, it would be more correct to say the reactions of the bichromate upon the gelatine itself under different conditions and before its exposure to light. This is a point which, if not entirely disregarded, certainly has not received that amount of attention which is commensurate with its importance.

It not infrequently happens that an experimentalist will take up a process and work it in strict accordance with the directions and formula given, and yet he will entirely fail in obtaining anything approaching a successful issue. Another, working with precisely the same formula and apparently under the same conditions, on the contrary, will succeed in securing a result of the most satisfactory character. Now, both may have kept absolutely to the same formula, even to using the same kind of gelatine—upon the character of which much at all times depends; yet, upon comparing notes, these two experimentalists fail to detect wherein lies the discrepancy in the results at which they have each arrived.

If an expert be consulted, the first suggestion probably will be that the two samples of gelatine employed were of a different character, the one being suitable to the particular process in question and the other the reverse. A further opinion, generally hazarded on similar occasions, is that the cause of failure is due to the bichromated film being dried too slowly and at too high a temperature, or, perhaps, too rapidly. The conditions under which the films were dried are certainly some of the most prolific sources of failure or success in many of the processes which are dependent upon the solubility of the gelatine after exposure to light, as in the case of the stannotype, the Woodburytype, the carbon, and processes of an analogous character. This branch of the subject has, however, so frequently been treated in these pages that it is quite unnecessary to dwell further upon it on the present occasion. Our object now is to point out another cause of failure which frequently arises when the films are formed in the sensitive state; that is, when the bichromate is added to the solution of gelatine before the film itself is produced, as is the case with many processes.

We are led to these remarks after reading the paper by Mr. W. Lang, Jun., on *Poiterin's Photo.-Relief Process*, which he read before the last meeting of the Glasgow Photographic Association. In his communication, after giving the formula for the gelatine mixture employed, Mr. Lang says:—"A concentrated solution of bichromate of potash was added to the warm gelatine *just before using.*" The italics are ours. Now the time of the addition of the bichromate to the gelatine is an important point in connection with many processes beside the one in question; and its importance is not very generally recognised—at least by those who have had but limited experience in this particular direction. The importance to be attached to the time that the bichromate is in contact with the gelatine while it is in a fluid and, consequently, a heated condition is very often overlooked in describing the working details of a process; or, if it be mentioned at all, it is very often unheeded by the experimentalist, and this frequently conduces to want of success or uniform results.

Let a solution of gelatine of a soluble kind be prepared and divided into two parts. To one let a given proportion of bichromate of potash be added, the mixture kept in a fluid state for (say) a couple of hours, and afterwards a film be formed with it—either on paper as in the carbon process, or on glass as in the Woodburytype. At the same time let a corresponding film be produced with the other portion of the gelatine solution, but, in this instance, with the same proportion of bichromate added immediately before using. Then let both films be dried under precisely similar conditions, and afterwards printed under identical circumstances.

Upon developing these two films a very marked difference will be observable between them. The one in which the bichromate was added at the last moment will, doubtless, develope rapidly and without the slightest difficulty; the other, on the contrary, will be very difficult to develope, if it do not prove to be absolutely insoluble. This, in all probability, will be the case, particularly if the temperature at which the gelatine was maintained had been at all elevated. If, however, a picture can be developed, a considerable difference will be perceived in the sensitiveness of the two films. That in which the bichromate was added just prior to the film being made will probably require as much as twice or thrice the exposure of the other. This simple experiment will serve to explain several of the discrepancies which at times have been met with when experimenting with bichromated gelatine processes.

It will now be manifest, in making comparative experiments with bichromated gelatine films generally which are prepared in the sensitive state, that in all instances the bichromate should be added as nearly as possible the same time before the film is formed or becomes set, in order to obtain uniform and reliable results. From the foregoing it will be seen that if a large quantity of gelatine, with the bichromate in it, be prepared at once and considerable time elapse before it is used up a marked difference in sensitiveness, solubility, and general behaviour may be anticipated between those films which are first and those which are last produced.

From what has been said it will be pretty obvious to all that the larger the proportion of bichromate salt present in the gelatine, and the higher the temperature at which the mixture is maintained, the more exalted will be the sensitiveness and insolubility of the film. It is tolerably well known that moist bichromated gelatine films, practically, are not rendered insoluble by the action of light; but it is not so well understood that an insolublising action is slowly set up in the gelatine if it be kept long in a fluid condition with the bichromate in it, which action results in total insolubility when the film is dried.

THE LATE REV. F. F. STATHAM, M.A., F.G.S.

The amiable and genial President of the South London Photographic Society is no more. He died of bronchitis (from which he had been suffering for several days), on Tuesday last, the 22nd inst., at 7.30 a.m.

How much this Society, which he loved so long and so ardently, owes to him, besides its existence, will probably never be revealed. The sad bereavement is the more affecting from the circumstance that the "silver wedding" of the President and the Society was to have been celebrated in a manner becoming the occasion on the 10th of next month. Fitting preparations were being actively made for the auspicious event, including the presentation of a suitable testimonial to a president who, by his unflagging attention and kindly interest, had secured the affection and esteem of not only the members of the Society and of London photographers generally, but also of the numerous photographers from the provinces who have occasionally come to town to attend the annual technical meetings of the South London Photographic Society.

Mr. Statham had for many years been rector of the populous parish of St. Mary, Newington, London, and had endeared himself to everyone by his unremitting attention to his duties. We shall next week have a more extended notice of our deceased friend, accompanied by a portrait.

The interment will take place at Norwood Cemetery tomorrow (Saturday), at 4.30 p.m., the first portion of the service taking place at St. Peter's Church, Walworth, at 3 p.m.

Mr. S. D. McKellen writes, in connection with our last week's article on *Adapting the Camera to Lantern Purposes*, that the exact method described by us has been adopted by him and applied to every one of his new cameras. He rightly judges that this fact was not known to us when we wrote, or we should, of course, have mentioned it. The arrangement is, however, of sufficient value to deserve all the publicity we can give it.

Two new societies are announced—one at Nottingham, the report of the first meeting of which appears in the usual column; the other at Monte Video, probably the first organisation of that description in South America.

An unusual compliment has been paid to English journalism by one of our American contemporaries in the publication twice over of an article which appeared originally on "this side." As the subject matter of the article generally did not seem to warrant such special treatment we have sought for some tangible explanation of the extraordinary phenomenon, but have signally failed, unless—and the idea strikes us as too ludicrous to be accepted as a real explanation—the cause is to be found in the fact that the editor of the journal in which the double reproduction occurs is in the reproduced article spoken of as "that admirable example of the photographer, artist, operator, publisher, and man ———" (but, respecting his modesty, we reserve the name). If that be the explanation, then we are puzzled to know something else. Is it the suspicion of being considered a "photographer," an "artist," an "operator," a "publisher," or a "man" that most tickles our contemporary's fancy? Perhaps when the time comes round again in the June number for the third periodical republication he will supply the information as an append.

Every photographer takes an interest in incandescent lamps—that form of electric illumination with which photography seems connected through the name of Swan, though, as a matter of fact, it is the particular kind of electric light least suited of all for illuminating the sitter. The Paris Opera is to be entirely lighted by these lamps, and already the work of fitting has begun, four hundred being now in use. Six thousand is the entire number required.

Our contemporary, the *Chemical News*, contains a droll "notice to imposters." It appears that a large number of scientific men have been victimised by a fluent rogue, who passes himself off as a chemist in distress, and on the strength of his tale has received sums of money from all quarters. The editor of the *Chemical News* gives a general notice, "in the hope that the gentleman in question, being satisfied with the good haul he has got out of tender-hearted men of science, will in future devote his talents to harder-hearted men of the world, who are so much more able to indulge in the luxury of giving."

That such impostors are to be met with in photographic ranks our readers, doubtless, know too well, but they have generally walked from the last town (usually a distance of forty or fifty miles) before they have ventured to press their tale upon those they interview. A close series of questionings will, however, in most cases dispose of their claims if the photographer have a fair acquaintance with or knowledge of his brother photographers. A contributor to these pages once had an experience very suggestive of the impostor the *Chemical News* describes. A distressed gentleman called upon him at his private residence, and represented himself as a private tutor belated. His story was disbelieved, and he departed, calling at a neighbouring house where ladies only resided. Quickly discovering the fact he so terrified the inmates that they gave him money to get rid of him. The next day he made his appearance at the said photographer's studio, a single night's rest having converted him into a photographer's assistant. He did not recognise the features of the photographer, and displayed considerable surprise when told he would be given into the hands of the police if he did not leave the neighbourhood at once.

In a recent address *On Engineering Progress*, the chief engineer of one of the American railways predicted that aluminium was destined at no distant day to replace steel for rails and bridge construction. We hope that it may not be distant, for then this most useful metal would doubtlessly find an immense field of utility in photography; but we much fear our hopes are built upon sand.

The use of nickel, however, has become thoroughly naturalised amongst us, and, whatever may be the probabilities as to aluminium, photographers will continue to make use of nickel as a plating to iron or steel. This plating is usually performed by the aid of electricity; but, according to Stolba, small objects can be satisfactorily coated without a battery. He gives the following directions for the purpose:—A concentrated (saturated?) solution of chloride of zinc is diluted with twice its volume of water. This mixture is boiled in a copper vessel, a few drops of hydrochloric acid being added if there should appear a precipitate of basic chloride of zinc. Next, a small quantity of powdered zinc is added—an addition which causes a deposit of zinc upon the vessel. Hereupon sufficient chloride or sulphate of nickel is added to the bath to give a distinctly-green colour, and the previously-cleaned articles are then immersed in the liquid in contact with zinc and allowed to remain there for fifteen minutes, the temperature being maintained at boiling point during the operation. If the coating be insufficient the articles are again immersed till the deposit is of sufficient thickness. In this way he claims to be able satisfactorily to coat articles of zinc, cast and wrought iron, steel, and copper.

The following formula is recommended for a cement for fastening together articles of brass and glass:—One part of caustic soda, three parts of resin, and five parts of water, and then kneaded into half the usual quantity of plaster of Paris. The cement will stand heat very well, and hardens in from one-half to three-quarters of an hour. If zinc white be substituted for the plaster of Paris the hardening will be slower.

At a meeting in the Parker Museum at the close of last month, the chair being occupied by Sir Joseph Lister, Bart., a most interesting demonstration was made before a distinguished audience by Mr. Watson Cheyne, of a subject which is attracting world-wide attention at the present time—the great group of minute organisms known under the name of *Bacteria*. These minute forms of animated matter play a vast part in the economy of nature, decay and disease being inseparably linked with them. Most of those fell diseases that in the history of man have destroyed millions of his kind are set down to the presence and growth of these animalculæ, each disease having its own characteristic bacterium. A complete knowledge of their peculiarities of size and conformations is necessary to the spread of a knowledge of their properties, and, in consequence, of a possibility of finding a remedy against them, and here photography plays a most useful part. They cannot, however, be photographed just as they are found, and they require to be stained with certain chemical preparations before being placed in the micro.-camera—some needing one stain, and others a different one. Details of the manner of doing this which have been found most useful by experts we may bring before our readers at some future time. Dr. Robert Koch, at the meeting we speak of, exhibited a large number of these photographs upon the screen, and they were inspected with the closest attention. Investigations into the nature of these marvellous bodies are, comparatively speaking, in their infancy, and we may be sure that photography will play no mean part in elucidating them.

LIME-LIGHT EXPLOSIONS AND THEIR PREVENTION.

I have read your sensible leading article on *Lime-Light Explosions and Their Prevention* with much pleasure, and agree with you that, in the words of the old proverb, "it is easy to take a horse to the water, but it is not so easy to compel him to drink." Still it may be hoped that lantern exhibitors generally will be wise in time, or they may, by-and-by, have to lecture to empty benches.

You recommend back-pressure valves as a preventive of lime-light explosions; but I think one reason why they are not more in favour is that there are little practical difficulties in using them. The metal valves are apt to "stick" and the oiled silk to become porous, so that at last the gas passes almost as easily in one direction as in the other. I have lately used thin vulcanised rubber sheeting in my Chadwick valves with advantage; but care must be taken not to screw them up too tightly, or the india-rubber will cockle and make the valve leak.

Hemming's safety tube is perfect of its kind, but scarcely available for the lime light, as the chlorine in the oxygen would be sure to rust the wires. I used this tube for years in King's College, London, and never knew an instance of the oxyhydrogen flame passing back into the receiver; but then the flame was burnt near the mouth of the tube, and there was no forcing nor suction. When safety tubes fail in the lantern it is, without doubt, from one of these two causes. The latter—namely, suction—can be prevented by the use of back-pressure valves, but the former only by placing the safety tube in the *front part* of the jet immediately above the mixing chamber; and this, in the case of an old jet, is not always convenient. I have proved that the pumice safety tube, alluded to in my paper, will resist a considerable amount of forcing without allowing the flame to pass; but it will not stand the "exhaustive testing" proposed by Mr. Lewis Wright. On connecting one of these pumice chambers with the H end of the jet by means of a long tube of stout vulcanised rubber, and then closing the O tap of the jet so as to allow no room for recoil, I succeeded in driving the flame quite through the pumice and shattering the balloon on the other side. In this case the volume of the gas was large and the expansive power on explosion sufficiently great to overcome the resistance. I might, perhaps, have prevented it by using a longer column of pumice, but then another difficulty would have arisen, viz., diminished pressure of gases and diminished light.

Altogether the subject is one which requires consideration, but I believe it will eventually be worked out to a satisfactory conclusion. Why, for example, could not a metal valve be placed immediately in front of the safety chamber to break the violence of the explosion and partially close the tube? Or, as an alternative, a side opening might be made, stopped with a cork or a valve. Some vent must be found for gas exploding, unless the volume be very small; and if an outlet be not provided it will either burst the rubber or force its way through the safety tube.

The best plan would doubtless be to construct the jet in the first instance with a small chamber, of about half-an-inch in diameter by half-an-inch in length, immediately below the nipple, to be filled with pounded and sifted pumice or with the finest shot procurable, or with coarse emery powder. If, in addition, a back-pressure valve were placed on the nozzle of each gas bag I believe you would have "a burner by which an explosion would not be possible by accident, by carelessness, or by design."

Since writing the above I have received the Journal of the 18th instant, containing a report of the meeting of the Edinburgh Photographic Society, and also a communication from Mr. G. R. Baker, to which I hope to reply next week.

T. Frederick Hardwich.

STANNOTYPE.

No. X.

At this stage the process of stannotype may be said to end, inasmuch as the subsequent printing operations are in all respects identical with Woodburytype. Stannotype is, in fact, merely a simplified method of producing a printing-mould from which proofs on gelatinous ink can be made.

The printing-press, as used for this purpose, consists in its improved form of an accurately-planed iron bed, to one end of which is hinged an arched beam carrying the top plate of the press, which is also accurately surfaced. The top plate is attached to the arch of the press by means of a screw and binding clamps, a ball-and-socket arrangement allowing it to be fixed in any position with regard to the bed of the press.

When the mould is ready for printing two or three thicknesses of stout blotting-paper or "drying-board" of the same size as the mould are damped and laid upon the bed of the press with the relief superposed. The three clamping nuts having been loosened and the top plate allowed perfect freedom of movement, the press is closed by means of the lever handle provided for that purpose. The top plate will now lie in contact with the upper surface of the mould, and, provided all the surfaces are true, there will be perfect contact. The middle screw under the arch of the press is now tightened, by which means the top plate is forced into contact with the mould. In this manner the degree of pressure is varied according to the requirements of each particular mould. The top screw is then tightened, which clamps the top plate firmly to the arch of the press, and, finally, the bottom screw, which governs the ball and socket, and fixes the position of the pressure surface. If the press be now opened and the top plate lifted it will always return to precisely the same position and with an equal degree of pressure.

The mould is prepared for printing by wiping it over with a piece of flannel saturated with a mixture of paraffine and olive oil, as thin a layer of grease being left on as possible. This operation is to be repeated after pulling each print, in order to enable the gelatinous ink to leave the mould. If any portion of the surface escape oiling the print is nearly certain to stick and tear away the tinfoil, necessitating the removal of the old and its replacement by a new facing.

The ink is composed simply of coloured gelatine, which may, we believe, be purchased in a concentrated form, requiring only solution in warm water. Those who prefer to make their own ink can, however, easily do so. A thick solution of any good, *hard* gelatine, varying in strength from fifty to eighty grains to the ounce according to the temperature and season, forms the basis. This is coloured by means of indian ink with a little alizarine or purpurine added to give warmth. A very convenient liquid indian ink is obtainable at the establishments of most artists' colourmen. The alizarine or purpurine are dissolved in strong ammonia, and added as desired to the blackened gelatine, very little being required to produce the desired effect. If the ink be made up with the addition of ten to twenty per cent. of alcohol it will keep for a very long time.

No hard and fast rules can be laid down as to the exact composition of the ink, as this will vary not only with the season and temperature but also with the depth of the relief and the nature of the subject. The chief points to be observed are that more gelatine will be required in hot weather than in cold, in order to compensate for the retarding action of the increased temperature on the setting of the ink. As regards the colouring matter: this should be increased in inverse proportion to the depth of the mould, a shallow mould or one deficient in contrast requiring more colour than a deep, well-contrasted relief. However, half-an-hour's practice at the press will teach the operator more than a volume of written instruction.

The paper employed is of a special character, made expressly for this purpose. Ordinary photographic paper of good quality and even texture is treated with a solution of shellac in borax, and then submitted to heavy pressure between steel rollers or plates, by which means a fine, smooth, and impervious surface is imparted, which prevents the ink soaking into the paper and destroying the purity of the lights. The whole secret of success in this style of printing rests in the paper, and to attempt to make shift with inferior or unsuitable paper is simply to waste time.

We now proceed to the actual operation of printing. The ink, carefully filtered into a convenient-sized bottle or jug, with suitable arrangement for keeping it at the proper temperature, is placed ready to the right hand of the press. The paper, cut to size, is also placed within easy reach, and clear of the greasy flannel used for oiling the relief. The mould having been properly levelled and oiled, as already described, the press is opened and a pool of ink poured on to the centre of the printing surface. A piece of paper is taken and dexterously, but without hurry, laid over it and the press closed. The paper is "sprung" into a curve and laid down upon the mould in the same manner as in sensitising albumenised paper. Upon closing the press the superfluous ink is squeezed out at the edges of the mould and collects in a groove at the edge of the bed of the press, whence it may be removed in the solid state and remelted when necessary.

The ink which escapes at the edges will serve as a guide to the time necessary to allow the picture to set. Thus, as soon as the surplus ink from the last closing of the press has become firm the press may be opened and the print removed without fear. This is done by simply lifting it by one corner, and slowly, but firmly, peeling it away from the mould. It is then laid face upwards on a sheet of plate glass and the thick mass of solidified ink removed from the edges by means of a steel spatula. The print is then ready for the next operation of "aluming," if that operation be considered necessary, or otherwise, for drying.

A word may be said as to the necessity for observing a proper temperature when using the ink. If it be too hot it will take longer to set, and so slow the printing operation; while its greater thinness will cause it to run away from the higher lights under pressure, and so produce hardness and patchiness in the prints. If too cold it will partially set before the press can be closed, with a result that may be readily imagined.

The first adjustment of the press will rarely be found to be exactly adapted to the requirements of the mould; but an examination of the first proof will show what readjustment is required. Thus, the pressure may be too great, or *vice versâ*, or the top plate may not be in strict parallelism with the printing surface. Again: the ink may be too dark or the contrary, or a thousand-and-one little details may strike the eye of the practised printer, who will know how to remedy or modify them.

With regard to the "fixing" with alum: though not absolutely necessary, many persons prefer to adopt it as an additional safety. If not so fixed or hardened the picture, of course, remains soluble in warm water, and so is liable to damage. The fixing process consists in immersing the prints for from five to ten minutes in a saturated solution of alum (carefully filtered), after which they are rinsed in one or two changes of water and hung up to dry, when they become practically insoluble.

There is nothing special to be said with regard to the drying, except that it is important here, as in every other portion of the process, to avoid dust, owing to the sticky nature of the surface of the moist print. When dry the prints are trimmed and mounted in the usual way.

ELIMINATION OF HYPOSULPHITE OF SODA.

We have lately had occasion to investigate the condition of a number of silver prints which, about twelve years' ago, were made under test conditions as regards the probability of their fading owing to presence of hyposulphite of soda.

While it is known that several substances—peroxide of hydrogen and hypochlorite of lime, *inter alia*—will decompose the minute traces of hyposulphite of soda left in a print as the result of hasty or imperfect washing after fixation, without injurious action upon the print itself, provided a sufficient degree of dilution be practised, the anti-hypo. agent in the case in question had been one of the salts of lead—the acetate. We may here observe that the prints referred to had successfully withstood the ravages of time, when such is understood to be confined to the period above mentioned. Indeed, there is a certain degree of justification in speaking of twelve years as quite a respectable period of duration in the life of a silver print, when it is well known that many succumb before the expiration of four or five years.

The strength of the lead bath necessary to ensure the safety of silver prints, so far as such safety can be ensured by the removal of the hyposulphite of soda, is about one grain of acetate of lead to an ounce of water. The method of employing it is to fix as usual in a solution of hyposulphite of soda, rinse the prints in three or four changes of water, then transfer them to the lead bath, in which they may remain from five to ten minutes, concluding with a final washing to remove the lead. The whole operation occupies far less time than is considered necessary to remove the hyposulphite by simple washing, while it ensures the desired end being attained in an effective manner.

One of the readiest and best tests for the presence of hyposulphite in a solution is that which is so well known and often described as the iodine and starch test. Upon a print having been cut in two parts, and one half quickly and somewhat roughly treated with the lead in the manner above described, while the other was allowed to soak in water, occasionally changed, during an entire day, the former showed by the test mentioned not the slightest presence of the fixing agent, while in the latter its presence was quite apparent.

In the olden times—that is, between the years 1840 and 1850—the salts of lead were frequently employed by calotypists in eliminating hyposulphite of soda from their prints. It then became *passé*, or was permitted to fall into a state of desuetude, eventually being rediscovered or resuscitated in America by Mr. Henry J. Newton, a New York amateur, who is now justly entitled to the honour of its modern introduction.

But, however anomalous it may appear, we do not hold the opinion that hyposulphite of soda, *per se*, induces fading in a print; for, as we have already placed upon record, and as the experiments and opinions of others will confirm, a print, otherwise properly treated, may even at a final operation be immersed in a (weak) solution of this salt (sodium hyposulphite) and dried without subsequent washing, and remain quite good for many years, retaining its pristine brilliancy. This was, in days of yore, also specially noticed by M. Blanquart-Evrard, Mr. Thomas Sutton, and others.

TISSUE FOR BURNT-IN ENAMELS.

Experiment with the transfer process of Lieut. Pavloffski demonstrates that by making the mixture of gum, honey, and bichromate up as a tissue, not only is there more certainty in the result, but the firing is much facilitated, as the collodion is apt to deflagrate and spoil the image, and also prevent the glaze from burning to the proper brilliancy unless the tablet be overloaded with glaze flux.

This modification is not published for the mere motive of making a different formula, but for the reason that in the writer's hands the process as published did not realise expectations; therefore, the modification was tried, and success was the result of the initial trial, which was repeated with subsequent ones.

Of course there is nothing novel in this change of procedure, as the process as published by Lieut. Pavloffski is upon the same lines as Swan's original carbon process, which was soon afterwards altered in a similar way, with the result that the modification has entirely superseded the original method.

The formula that was successful is as follows :—

Gum arabic	1 ounce,
Water (boiled)	12 ounces,

dissolved by the aid of very gentle heat in about eighteen hours. Strain first through muslin and then through flannel. Now take a tube of Hancock's china colour (for water) and mix the contents with three drachms of honey in a mortar by means of an ivory spatula; then add by degrees the above solution of gum, and when thoroughly mixed add two ounces of a saturated solution of bicromate of potash and strain through three thicknesses of fine muslin.

Now polish a piece of glass of any convenient size and smear with a little vaseline, which polish off with a clean linen rag; then spread a comparatively thick film of the sensitive compound, and place the plate upon a levelling-stand until semi-dry. A piece of plain Saxe paper cut to size is now damped, and, after being laid in position over the tissue compound is lightly squeegeed into contact; and the plate may be placed away to dry in a closet at about 120° Fahr., or in front of a fire, and when the desiccation is complete the film adhering to the paper backing is stripped off. Safe-edge the negative to be printed from, and expose for about half the time that a carbon print would require.

Prepare the enamel tablet by washing first in a weak solution of soda; then rinse and apply a weak mixture of water and nitric acid. Again rinse and coat with a filtered solution of—

Gum arabic	1 drachm.
Water	5 ounces.
Saturated solution of bichromate of potash	½ drachm.

Then dry and expose to light, so as to harden the film.

The exposed tissue is dipped in cold water, afterwards squeegeed into contact with the prepared tablet, allowed to stand for a few minutes, and then immersed in tepid water. Strip off the paper backing and at once transfer the tablet to cold water, gently laving the picture until the development is nearly complete. Then place in a dish containing a mixture of water twenty ounces, methylated spirit one ounce; transfer to another containing equal parts of water and spirit, and finally to one containing methylated spirit only.

The picture is now dried by the aid of heat, and then coated with a varnish of oil of tar and essence of lavender. When this becomes tacky dust upon it a glaze or flux powder by means of a small pepper dredger, and place the tablet at the mouth of the furnace until evenly heated throughout; then transfer into the muffle, and in a few minutes the firing will be complete.

The process is much simpler and the manipulations easier than either the dusting-on or the substitution method.

It cannot be said as yet how long the sensitive tissue will keep in good condition; but, judging from the life of bichromated pigmented gelatine, a week will perhaps be the limit. To obviate the necessity, therefore, of preparing the tissue throughout as wanted, omit the bichromate in the formula, sensitise the tissue by immersion in a two-per-cent. solution of bichromate as required, and dry in front of the fire. "Gup."

ON THE PREPARATION OF GELATINE PLATES.

[A communication to the Bristol and West of England Amateur Photographic Association.]

In taking up this subject upon which to read a paper before the Association I do so with a considerable amount of diffidence, as it has been so fully and ably treated in the journals by those who have been able to devote not only their spare time but the whole of their time to it—both theoretical and practical students.

However, as I have, ever since I adopted the gelatine process, made almost all the plates I have used, I am perhaps somewhat qualified to offer some few remarks upon this subject, which remarks I shall endeavour to make of as practical a nature as possible. In this determination I am perhaps somewhat strengthened by the belief that much assistance can be given by verbal explanation and ocular demonstration which written treatises will not adequately convey, and by certain inquiries made by various members which have seemed to imply a desire that I should give such demonstration. This being so, I cheerfully accede to the request, if by so doing I can impart information or render any help, even in any small degree.

I shall endeavour to treat the subject under two heads, namely, *Formulæ and What to Avoid*, and *Modus Operandi and Dangers Incident Thereto.*

Formulæ and What to Avoid.

Primarily I would say hereon—"Adhere to what is simple, and when you get a good formula that suits you in all respects stick to it."

Gelatine plate-making requires much system and as much uniformity as is possible, so that by often searching for novelties or being led away by much-belauded formulæ, when one is already working a process which gives certain and reliable results, there is great danger of sacrificing a certainty for an uncertainty, and wasting much valuable time, which, in the present day, I am sure no one can afford to do.

The formulæ may be classed under two heads, namely, those involving digestion, and others boiling. The former has been a very favourite method for somewhat slow plates; but I cannot help recommending those desirous of making plates to adopt the latter course, namely, boiling where possible, because much time is thereby saved, half-an-hour or so taking the place of twelve or fourteen hours. Greater certainty is assured, the temperature during digestion sometimes creeping up in a most unsatisfactory manner during the operator's absence, the emulsion being thereby damaged. For a business man it is far more convenient, as the whole operation can be completed during the leisure of an evening, when in the other case the stoppage of the digestion arrangements for setting, &c., &c., have to be conducted very often at a time when one's thoughts are being drawn towards the shortly-to-be-encountered business of the day, resulting in hurry and a want of deliberation not conducive to careful and satisfactory manipulation.

Of course in a paper such as this it is impossible to go into the thousand-and-one varieties of modes of getting more or less at the same end, especially as, to a certain extent, one must perforce be guided by the difference of taste regarding speed, colour of plate, mode of development, &c. I may, however, give my own ideas as to the class of formula which, taken altogether, is the most desirable.

I do not feel at all drawn to those formulæ which include amongst their ingredients chloride; for my experience has been that the result is a cold, grey colour, neither pleasing in appearance nor facilitating the judgment of density. I have found the most reliable plates, and those possessing most vigour in every respect, accompanied by clear shadows and a general appearance of pluck, together with a rich warmth of colour in the resultant negative, have been prepared with an emulsion containing iodide; and, so far as my own practice is concerned, I see no prospect of my omitting this from my emulsions. The negatives I have brought for your inspection are those from which my pictures exhibited at the Bristol International Exhibition were printed; and I think I may say that they are more of the wet-plate class of negative than a good many gelatine negatives one sees—alike as regards colour, clearness, and general pluck. They were all prepared with an emulsion containing iodide.

Another important point—in fact, the all-important one—in the make of the emulsion is the complete, rapid, and yet steady admixture of the bromo-iodide and silver. For this purpose, various nicely-constructed rapidly-revolving whisks and emulsion vessels have been constructed; but I consider we are all of us greatly indebted to the mode lately introduced by, I believe, Mr. W. K. Burton, and which method commends itself to me as being the most perfect (and almost automatic) that we could possibly possess. Instead of pouring the solution of bromo-iodide into that of the silver, the dry silver in crystals is placed in a hot stone bottle, all the bromo-iodide solution is poured into it, and it will at once suggest itself to you that only as the crystals dissolve can the compound be formed, and thereby a steady and complete mixture is formed, only requiring vigorous shaking till the crystals are heard to rattle no more. I have been exceedingly pleased with this new idea, and can most certainly say that the results, as regards fineness of film and regularity, have been in my hands all I could desire.

We next come to a point upon which it is quite impossible for anyone to make any definite statement with reference to what is correct or what is incorrect, each class being most desirable and suitable in its respective sphere—I mean the rapidity of plates.

For my own part, I prefer for general landscape work a plate of about five times the rapidity of an average wet plate. I am inclined to think that much beyond this involves the danger of a probable loss of pluck and clearness in the shadows; also an absence of latitude in exposure and treatment very desirable as qualities in a plate for general landscape work. Of course, I do not for a moment under-estimate the great value, in frequent cases, of rapid plates, and always take a few with me when out for a day's photography.

MODUS OPERANDI, AND DANGERS INCIDENT THERETO.

Under this section I shall have to say but little—that is, not accompanied by demonstration—so that if it be somewhat disjointed I must beg you to excuse it.

I need hardly say that one of the most important points in connection with the actual operations is extreme cleanliness. This requires more care and promptitude than in many other branches of the art, as particles of old emulsion are very liable to stick to and remain on dishes, vessels, &c., thereby causing mischief to fresh batches of emulsion, and being in frequent cases the cause of the failures so exercising the minds of operators. Great care is necessary in the choice of gelatine, and samples containing any grease (a most general defect) should be discarded in favour of those of purer quality, which should be both hard and soft, and mixed in the proportions which a few experiments will soon determine as the best suited to the manipulation and requirements of the operator. I find no brands of this material superior to Heinrich's and Nelson's "X" for hard kinds, and Nelson's No. 1 for soft. There is, I believe, another of this latter class made at Wintherthur, in Switzerland, which is also very good, but I have not tried it. There are three things which a would-be plate-worker should have arranged at the very outset of his endeavours, as being absolutely necessary for convenient comfort in working (and I maintain no man will succeed who is not comfortable in this work). These are a good levelling-cupboard, a spacious drying-cupboard, and a light-tight cupboard. You may say—Why a cupboard for levelling? Would not a large slab do equally well? A slab would answer the purpose, but would not do anything like so well; for if on any emergency you should be called from your room when coating, you have only to close your levelling-cupboard, when everything is perfectly safe till your return to complete the operation. This is a matter of great convenience. And, while on the subject, I may say that such cupboards should open and close easily, and with no makeshift fastenings; for it sometimes happens that one wants to get out a plate from the drying-box to test it in a hurry, and, unless the fastenings are simple and sure, it is very probable that the result will be a number of plates fogged whilst in the drying-box.

I may, perhaps, with advantage describe these two boxes. My drying-box is a little above the ground—say one and a-half foot—and the levelling-box above. The latter is fitted with six shelves, each accommodating six 10×8 plates, making a total of three dozen. The shelves are arranged in such a manner that on closing the box it at once becomes an additional drying-box. The drying-box proper holds nearly sixty 10×8 plates on edge, in two rows.

I will now make up a small quantity of emulsion, remarking, as a caution, that before commencing this operation the manipulator must be careful to see that he has everything well arranged and at hand, so that when in the dim light necessary to success—but none the less awkward for working by—he shall not have to hunt and grope about for things with the certainty of breaking not a few.

H. A. HOOD DANIEL.

[Mr. Daniel then fully described the mode, and gave a demonstration of the making of gelatine emulsion and coating plates with his revolving coating machine, and concluded with a few remarks on the development of gelatine plates.]

ON LENSES.

[A communication to the London and Provincial Photographic Association.]

IN treating upon the subject of photographic lenses certain optical terms have to be introduced, which will, therefore, be explained without going more deeply into the science of optics generally than is necessary for the intelligent consideration of the subject in hand.

Planes of Definition.—It is to be regretted that in such a science as optics, where the calculations are made upon very exact bases, such an incorrect term as "plane of definition" should have come into use. The surface upon which true definition is projected is almost always a curve. It must, therefore, be borne in mind that, if the expression "plane of definition" be employed in what follows, it is only to be understood in the conventional sense.

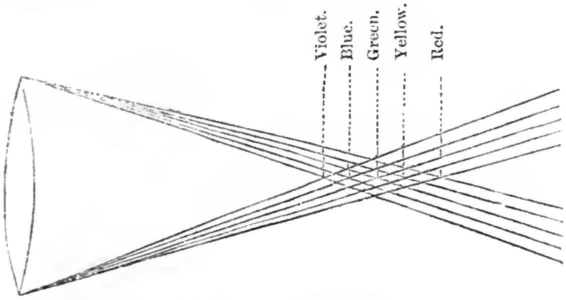
Focus, Equivalent Focus, and Conjugate Focus.—The focus of a lens is the place at which the rays proceeding from it meet to form an image. The word "focus" is also employed to mean focal length for parallel rays, and in the case of a single plano-convex or double-convex lens is ascertained by measuring the distance of the image which it gives of the sun, or any very distant object, from some point in the lens itself. With a double combination the expression "equivalent focus" is used to denote the focus which would be possessed by a single lens, giving an image of the same size as that produced by the combination. There are various means of ascertaining the equivalent focus of a combination. A very common one is to focus some object of the same size as itself, and then to take one-fourth of the distance from the ground glass to the object, as the focus required. This method is not quite accurate, for it takes no account of the effect produced by the separation of the lenses, and is not always practicable, as there may not be a camera extending sufficiently to give an image of the same size as the original. A method which I published in 1879, in connection with a proposal to introduce a standard of rapidity for lenses, which standard has since been adopted, is, I think, to be preferred. Focus an image of some definite proportion; then measure the distance from the ground glass to the original, multiply by the number representing the proportion, and divide by the square of a number larger by one than the number which has been used as a multiplier. Thus, if marks twelve inches apart are made, or a foot-rule be planted with a head-rest against the background, and these marks, or the length of the rule, are focussed to be three inches apart upon the focussing-screen, measure the distance from the background to the screen, multiply by four (the number of times that the image is smaller than the object), and divide by twenty-five. This will give the equivalent focus with only one-quarter of the error that exists when focussing the object of full size, and is quite near enough for the purpose required. Conjugate foci are the distances respectively of the object and the image from what is known as the optical centre of the lens.

Aperture, Angular Aperture, and Rapidity.—The aperture of a lens is its working opening as limited by the diaphragm. The angular aperture, often spoken of simply as "aperture," is the proportion between this opening and the equivalent focus of the instrument. It has been customary to denote this aperture by means of a fraction, f, the focus of the lens being the numerator, and the relation of the focus to the aperture being the denominator. Thus, $\frac{f}{4}$ describes the opening of an ordinary portrait lens, which, having a focus of twelve inches, has an opening of three inches. The rapidity of lenses is in inverse proportion to the square of the number used as denominator; but as the calculation of this is rather involved, it has been decided to accept $\frac{f}{4}$ as the standard or unity, and to reckon diaphragms by the length of exposure required in comparison with this unity. Thus, with a diaphragm of $\frac{f}{8}$, requiring an exposure of four times that required with $\frac{f}{4}$, the diaphragm is, on the universal system, numbered four.

It might seem unnecessary to add (but that I know it is not universally understood) that when from any reason a small stop must be used the most rapid lens is no more rapid—disregarding any variation due to colour or difference of reflecting surfaces—than the slowest one of the same length of focus which is capable of having the same-sized stop; so that if, in order to get what has been called "depth of focus," a small stop has to be used, there is no object on the score of rapidity in using a rapid lens, and perhaps a slow lens may from its other properties answer the purpose better.

Achromatic, Actinic.—The various rays which, compounded, make up white light are refracted or bent aside in different degrees. They are, therefore, dispersed as well as refracted, and those rays which possess the greatest chemical power, or produce the most effect photographically (particularly the violet), are more refracted than those, such as the yellow, which give the greatest visual power. The effect of this is that, with any simple lens, a series of images of different colours is formed at different distances from the lens itself. The image will be most distinct to the eye when the yellow rays are in focus, but will give the sharpest photograph at or near the place where the violet rays come to their focus. In a lens which is not corrected, therefore, the camera back has to be shifted a little in after focussing. The extent to which this will be required varies with the kind of glass used, but may be taken as from one-fortieth to one-thirtieth of the focal length. In the diagram, as in other diagrams, the amount is exaggerated in order to make it easily seen.

FIG. 1.

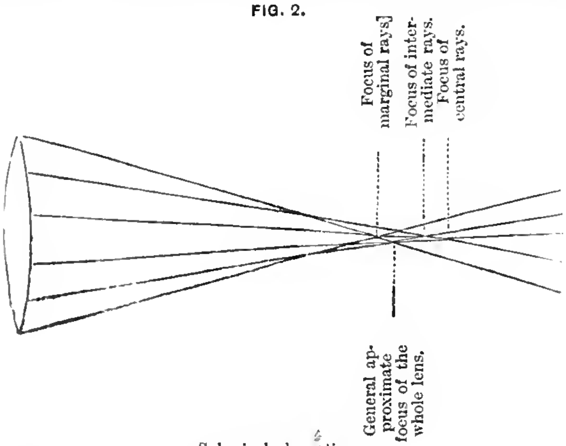


Chromatic dispersion by a single lens.

In uncorrected telescopes the evil is seen in coloured fringes surrounding light objects. Newton thought that the defect was irremediable, but it was afterwards found that different refracting substances dispersed the light in different proportions from those in which they were refracted, and, therefore, by uniting a convex lens of a substance of low dispersive power with a concave one of a substance of high dispersive power, it was possible to let the dispersive forces balance each other, and leave a surplus of refractive power in the convex lens to form an image. Acting upon this discovery Dollond, more than a century ago, constructed the achromatic (without colour) telescope. There is a slight difference between the amount of correction given to lenses for visual purposes and those for photographic use. The word "actinic" applied to lenses means that they are corrected for photography.

Spherical Aberration.—Spherical aberration is so important that it is well to understand clearly what it means. It is that characteristic by which the different parts of a lens uncorrected for this defect bring the same object to different foci. It is evident that this

FIG. 2.



Spherical aberration.

must result in confusion or want of sharpness. When an image is projected by an ordinary uncorrected lens, the marginal portions of the lens bring the rays which pass through to a focus nearer the lens than the focus of those rays which pass through the centre of the lens, and the rays passing through the portion of the lens between its centre and its margin are focussed at an intermediate place. This is called "spherical aberration," and where it exists perceptibly no truly sharp, well-defined image can be obtained, as every point is represented by a circle. The nearest approach to a distinct image is where the circle of confusion is small and the concentration of rays great, as marked in the diagram. If a stop or diaphragm be now used, cutting off the marginal rays, the focus will be lengthened to the point where the central rays meet

Aplanatic means without spherical aberration. W. E. Debenham.

(To be continued in our next.)

ACTINISM AND COLOUR IN THEIR RELATION TO DARK-ROOM ILLUMINATION.*

I will now mention another of Professor Tyndall's experiments, from which I think I have discovered an important point bearing on dark-room illumination. Having taken a piece of red ribbon and held it in the green rays of the spectrum, he found that the colours were quenched, but that heat had been generated; but when he held it in the red rays the colour was sent back to the eye unchanged. The quenching of the colour must, therefore, have resulted from the fact that the wave-lengths of both colours were lengthened to that of an invisible heat ray (I suppose I ought to say of an infra-red ray).

I also thought it was most probable that if a certain colour were reflected from or transmitted through a substance it would also pass through glass of the same colour unchanged, just as white light passes through clear white glass; and, if it were so, it would be useless to put two thicknesses of ruby glass of the same tint in a dark-room lamp, because if light passed unchanged through the second, one piece of ruby and one of white glass would do nearly as well. I say "nearly as well," because in the case of ruby glass the colour is only on one surface, and is not in the substance of the glass as it is in the green; therefore the colour is not so even. I further believed that if I placed on a piece of white paper a substance which reflected red light of exactly the same tint as my ruby glass the red colour reflected from the substance would pass through the ruby glass unchanged, and would be of the same tint as the white paper appeared to be when viewed through the ruby glass.

After trying dozens of experiments, with more or less success, chance came to my assistance. On looking through the ruby glass I noticed that the red ink in the well on my writing table looked like perfectly clear water. I at once wrote a few words in red ink and was pleased to find that on looking at them through the coloured glass *they were quite invisible*. This proved that when light had been brought to one wave-length by the ink the reflected colour had passed through the glass unchanged; if it were not so I should have seen the writing. I looked at the same paper through green glass, and the red ink looked black—indeed of a deeper colour than if it had been written with black ink. This evidently shows that it is unnecessary to use a number of thicknesses of the same media after we have once obtained a *pure, even colour*. Then we need simply cut off the power of the light, and for this purpose ground glass or white tissue paper would answer equally well.

I now come to the question—Why does Mr. W. E. Debenham's combination of green glass and yellow paper give a whiter light than either colour alone? We know that if we throw the blue and yellow rays of the spectrum on one point we obtain a pure white light. Mr. Debenham's colours, through not being perfectly complementary, evidently transmit the remaining portions of the colour together with the white light. But there are other combinations of colour which produce white light beside the blue and the yellow. The following are given in Ganot's *Eléments de Physique*:—Orange and Prussian blue; yellowish-green and red; yellowish-green and violet. Though to the eye all these produce the same pure white light, they would, most probably, have a very different effect when thrown on a sensitive film; and, from our knowledge of the actinic force contained in the different coloured rays, there seems no doubt that, if we could get pure colours, the white obtained by a combination of red and yellowish-green would be the safest for photographic purposes.

Again: the question arises—How is it that these various combinations of colour produce white light? It cannot be that, like the Kilkenny cats, they have annihilated one another; and as I could not see that an explanation was given by the absorption theory I have been thinking it over.

We know that in light there is a certain amount of actinism and luminous power, and that the two combined go to make white light. Now, it is very evident that as the combination of any of the two colours given above produce white light, *the combining colours must contain in themselves, without the addition of any other rays, those forces in exactly the same relative proportions that are necessary to produce white light.* This shows that white light does not consist of a great number of different constituent parts, namely, the ultra-violet, the seven colours of the spectrum, and the infra-red rays; but that they must all be due to the varying powers of two opposing forces, the intensity of which depends on the opposition which the different portions of the pencil of light meet with in their passage through the prism from the different points of incidence. Is not this another point in favour of my theory—that there are only two forces in light, and that the colour of each ray and the amount of actinic power in it is due to the different proportions of these forces producing that ray?

In reply to Mr. Macdougald's remarks: the example which he gives as being "on all fours" with that of light, viz., the three different properties of sugar, is not to the point, because if he take an ounce of sugar and divide it into seven equal parts the grains in each part will be equally translucent, equally soluble, and equally sweet; but if we divide white light into seven parts (viz., the seven colours of the spectrum) by the prism, we find that each part contains different proportions of actinicity and luminous intensity. The present theory that refrangibility, actinicity, and luminous intensity are inherent properties of one set of vibrations in one light-carrying medium does not explain the *causes* why these inherent properties are present in varying proportions in each ray.

The reason my first article on this subject was written was to ask whether it would not be better to treat them as distinct forces. Old

* From pressure on our space we have been compelled to leave over this article for several weeks.—Eds.

experimentalists, adding heat to the number, treated them as such; but they made the mistake in thinking that the prism split up the pencil of light into distinct divisions.

The theory of the inherent properties is like a countryman's explanation of the contents of a London sausage:—First of all he cut it up into equal portions. In one portion he found a greater amount of a mysterious white substance, and less of a no less mysterious red substance, than in another, and he explained the matter by saying "these are inherent properties of a sausage." He might have been justified in leaving the subject at that point, because the amount of white or red substance in the different portions is not governed by any fixed laws; but in the case of light it is far different.

A diagram was exhibited by Captain Abney in a lecture given at South Kensington, in 1876, in which the maximum of actinic force in a pencil of light transmitted through a prism on to a film containing silver bromide was shown to be at G. I ask—does not this prove that there is a force in light governed or controlled by some other force? If it were not so there would be no reason why actinic force should not be as powerful at the B as at the G lines. The amount of heat at the different points of the spectrum, as shown in a diagram by Professor Tyndall, proves that with the decrease of actinic force we get an increase in the length of the waves towards the ultra-red rays. This indicates that in order to obtain a safe light for dark-room illumination we must use a medium which will allow the long wave-lengths to pass freely, but which will stop the short ones, and with them actinic force; or, I should say, it must lengthen them, and render the vibration slower. There are certain of the elementary liquids—bromine for instance—and also solutions of the solid elements—such as sulphur, phosphorus, and iodine—which do this to a great extent. I am at present engaged in experiments in which I am using a saturated solution of iodine in place of coloured glass or paper. Theoretically this would help us in obtaining a safe light, and shortly I hope to show practically that it does so.

In Professor Stokes's experiments on the invisible ultra-violet waves he proved that, by causing them to impinge on a paper wetted with a saturated solution of sulphate of quinine and afterwards dried, they were brought within the range of vision in consequence of the vibration being made slower and of greater wave-length. In my last article I mentioned that by Professor Tyndall's experiment the visible rays were lengthened to the length of invisible heat rays through being thrown on black ribbon. How will the absorption theory explain these facts? How can a thing be said to be absorbed or annihilated when it is changed into something quite different? HERBERT S. STARNES.

[In connection with Mr. Starnes's previous article we were compelled to say that we could not hold ourselves responsible for his views, and the same remark applies with even greater force to his present one. It is really no use discussing a subject upon the basis of a series of new theories, or rather hypotheses, which none but their originator can accept. If Mr. Starnes had carefully studied the authorities he quotes so freely, he would scarcely have committed himself to a statement of belief that because certain colours of the spectrum superposed produce white light that such colours employed in the form of glass screens would transmit a white light safe for photographic purposes. The safety under the latter conditions would be undoubted, if safety can be said to be a necessary accompaniment of absolute darkness. Nor do we think that any of the authorities will support Mr. Starnes in his argument that white light is "due to the varying powers of two opposing forces"—actinism and luminous power. The fact that "chance came to his assistance" to teach him that characters written in red ink upon white paper are invisible when viewed through glass of the same colour, seems to prove that Mr. Starnes, while attempting to elucidate the more abstruse questions connected with light, has neglected to study the elements of that science, otherwise he would have been acquainted with a circumstance familiar to every schoolboy of a bygone period, when science teaching had not reached its present stage of development. One more instance of the writer's illogical arguments is to be found in the suggestion that two thicknesses of ruby glass are no better than one in a dark room, because the light passed through one would also pass through the other unchanged. As well might we say that one sheet of tissue paper will have the same effect in stopping light as a whole ream! Seriously, our columns are kept open for the purpose of discussing matters of practical photographic interest—not of ventilating new hypotheses which, so far as we can follow them, seem to be quite at variance with observed facts. Here the discussion must close.—EDS.]

NOTES FROM THE NORTH.

At the request of my friend, Mr. Alexander Henderson, of Montreal, Mr. John Parker, of Glasgow, has recently sent me a description and drawings of a sky-shade devised by the former on the lines of the very useful instrument invented by the latter, but modified so as to be workable in the rigorous climate of Canada West. Mr. Henderson writes appreciatively of the efficiency and simplicity of Mr. Parker's *shade*, a description of which appeared in the number of this Journal for November 9, 1883, but says that the photographers whom business or pleasure take as far west as the Rocky Mountains, frequently having to work in a temperature of 20° or 30° below zero, cannot, with the indespensable fur gloves, tear or cut the paper to the required shape, and to overcome that difficulty he has devised the following, which the drawings will fully explain.* *Fig.* 1 is a front view of the lens, with the shade arranged for a picture with distant mountain at the head of valley and trees at sides. A, narrow strips of brass, grooved and tongued like ordinary flooring. B, the brass frame, in which they slide easily, the necessary friction being got by turning the milled head C. D, the rod by which the shade is attached to the support E (*fig.* 2), to which it is hinged just firmly enough to remain at any desired angle and to move easily when required. *Fig.* 2 is a side view of the lens, showing the method by which the shade is attached, the dotted lines indicating it partly raised. Those who remember the description of Mr. Parker's sky-shade will see that the only material difference between it and that just described is the substitution of permanent sliding strips of brass for the temporary pieces of paper or cardboard, and no doubt the substitution will effectually answer the purpose which Mr. Henderson had in view. Mr. Parker's shade, either as originally introduced or in its improved form, should have a place in the "kit" of every photographer who aims at including clouds in his pictures, or wishes to place the distant hills and the near foreground on his negatives in something like the relation they bear to each other when seen by the eye.

FIG. 1.

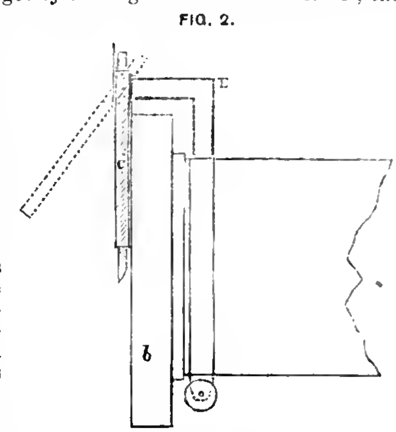
FIG. 2.



b, Front of lens tube.

The "ethoxo" light is having a bad time of it, but not worse than it deserves. The readers of the Journal will probably remember that, several years ago, I sounded a note of warning when the vapour of sulphuric ether was first proposed to be substituted for hydrogen in the production of the "lime light." I wrote feelingly on the subject, as I had for a number of years carried embedded in my muscular tissue certain pieces of glass, the result of such an explosion, and naturally thought that if such accidents occurred in the hands of those who had been trained for half a lifetime to the handling of dangerous substances they were much more likely to happen to those whose practice was regulated by "rule of thumb."

That the "ethoxo" apparatus, as constructed by its inventor, can be worked with safety and give a very brilliant light I know, as I have assisted more than once at exhibitions where it was employed; but *I knew the operator*, and that makes all the difference. The average peripapetic "magic lantern showman" knows just enough to get a good light when all goes "as it used to do," but is utterly incompetent to successfully overcome a hitch or correct anything abnormal in his arrangements; and I would as soon smoke my pipe in a powder magazine as stand beside him while using the "ethoxo" apparatus. I, therefore, heartily endorse the first recommendation of the jury in the Chadderton explosion case, to the effect that "ether-oxo gas should be prohibited at all public entertainments."

I see that Mr. A. Duthie, at a recent meeting of the Glasgow Photographic Association, tries to revive the old scare of hypo. in the mounts, and that "Free Lance," in taking him to task thereanent,

* The generic idea of this shade has been so frequently published in this Journal, or its ALMANAC, as to leave us a little in doubt as to who was really the first of those whose claims to its paternity are before the world. Among those whose names we at this moment recollect in such connection, as independent inventors, are Messrs. Baynham Jones, G. S. Penny, and W. M. Ayres. But, unless we are misinformed, a shutter of this class was on exhibition in the editorial office of this Journal nineteen years ago. Query: Who was *its* inventor?—EDS.

seems to imply that he also is a believer in the presence of that deleterious substance in at least some of the cardboard employed in mounting prints. I should like to know the test on which Mr. Duthie relies as a proof of the presence of hypo. So far as my memory and the pages of the Journal may be relied on, I think the test that has generally been applied is the blue starch iodide; and in an article on paper-making, published in THE BRITISH JOURNAL OF PHOTOGRAPHY some years ago, I showed conclusively—to my own mind, at least—that it is altogether fallacious. The reason is not far to seek. A trace of sulphurous acid discharges the starch iodide colour as thoroughly as a like quantity of hypo., and it is hardly possible for even a trace of the latter body to remain in the finished paper, while in some kinds of paper it is impossible but that the former must be present.

It is well known that hypo., under the name of "antichlor," is almost universally employed to get rid of the chlorine used as a bleaching agent; but anyone who has seen the extraordinary amount of washing to which the antichlorised pulp is subjected will easily understand that nothing short of spectrum analysis could detect the infinitesimal trace that can remain in the finished article. On the other hand, the "animal size" used in a large quantity of the paper manufactured in this country at least is, for technical reasons, made from animal matter approaching the state of putrefication. Sulphurous acid is employed as an antiseptic, and any washing that would remove it would also remove the size itself. *Verb. sap.*

JOHN NIÇOL, Ph.D.

THE PRESERVATION OF THE EYESIGHT OF PHOTOGRAPHERS.

As one who has given close experimental study during the past few months to everything published in these pages in relation to developing-room illumination, will you kindly allow me to summarise the practical results of the whole examination? The following are my conclusions, and all but the last one will probably be generally accepted; but, in defence of the value of that last one, I am prepared to do battle if need be.

To get the best results, and the best light for the comfort and preservation of the eyesight:—

A. Daylight should never be used as the original source of developing-room illumination.

B. The flame used should not be a bright white one, but yellowish. Green would be good if easily practically obtainable.

C. The coloured screen of the lantern should not be transparent, but translucent.

D. The light from the lantern should be at a low elevation in relation to the surface of the plate under development, an angle of about 40° or 45° from the top of the coloured screen being about the maximum.

E. The lantern window should be a very large one, so that the whole room is comfortably lighted up.

F. It is safest to *begin* the development a yard or more from the lantern window.

G. Under no circumstances should two coloured screens of the same material be used in the window of one lantern.

H. All lantern windows are faulty as regards comfort and preservation of the eyesight which do not possess at least one layer of a green colour.

The following are my reasons for advocating the foregoing eight rules:—

A. The chief reason why daylight should not be used as the original source of light is that it is so enormously rich in those actinic rays which photographers are striving to keep out of the developing-room. Why begin the operations with a maximum instead of a minimum of the adverse force? Another objection to daylight is the irregularity of its intensity, so that a coloured window which is safe at one time may be unsafe at another, and the operator, therefore, uncertain of the real cause when some of his plates begin to fog.

B. A yellowish flame is better than a bright white one, because it is less rich in those actinic rays which the operator desires to avoid. A candle, therefore, is better in a lantern than a paraffine lamp. In permanent establishments, perhaps, as good an easily-available light as any is that of an argand gas flame after the central hole of the argand burner has been plugged at the bottom by means of a cork. This stops the entrance channel of the air to the centre of the flame, and renders the flame longer and yellower.

C. The coloured window of the lantern should not be transparent, but translucent. When ground glass or tissue paper or other semi-transparent fabric is used the rays from the flame do not fall directly upon the plate, but are more diffused, and leave the window at a larger angle. Nearly all the light from such windows is actually reflected light, as in the Starnes' lamp. For instance: the water of the sea is transparent, but when broken into foam it is no longer transparent in the mass, but translucent. The rays of light are reflected in all directions inside and outside each of the innumerable microscopic drops of water in the foam, and finally reach the eye after myriads of reflections. It is the same with the transparent drops of water which build up clouds. So is it with powdered glass, or with paper. The light falling upon the vesicles of cellulose in paper is reflected and refracted in all directions numberless times before it escapes on the other side of the sheet of paper, and with each reflection it loses some of its actinic power, both because of the selected colour of the paper and because of the act of reflection itself; for the actinic rays have less power of penetration through coarse media than the red and yellow rays, which is why street gaslights look redder and yellower in a London fog the farther they are off. The true canary medium paper sent me by Mr. Fry owes its safety to its thickness, and consequently its power of breaking up the rays of light in its interior. Otherwise its colour is very inefficient for the purpose, and this may be proved experimentally by putting its component particles more in optical contact with each other by soaking it in gum-water; it will then be found to be as unsafe a sample of paper, so far as its colour is concerned, as could well be selected. The discussions on these subjects at the photographic societies will continue to be unscientific and desultory until these two elements of safety in any screen are distinctly specified and separated from each other by the readers of memoirs, and the true value experimentally determined by them for each. When fabrics are used as screens the authors of papers should state exactly the weight in grains per square foot of each sample of paper or fabric. This would give a rough idea to readers how far their thickness may form an element of safety. I am not in favour of thick screens, but of very thin ones, intensely coloured with light and brilliant, not dark-coloured, dyes—those, in short, which let plenty of light through, highly coloured. Oil silk specially made and dyed for the purpose would, I think, in time drive everything else out of the market. The fault of tissue papers and coarser fabrics is their irregularity; they are, actinically considered, full of holes, so that their "grain" can be printed through a single thickness of any one of them upon a gelatine plate charged with bromide of silver.

D. Figures to prove this point were given in a preceding article of mine. When the light falls from a higher elevation than 45° or 50°, a very large percentage of it reaches the sensitive plate in the dish, which light was previously reflected from the surface of the developer without reaching the plate. Thirty or forty per cent. of danger of fogging can be avoided by attention to this rule.

E. The lantern window should be a very large one for the benefit of the eyesight. There is no reason why it should not be the whole length of one side of the room, however large the room may be, and it should have a row of gas jets behind its long translucent screen. The intensity of light declines inversely with the square of the distance from the source, so the light from the long lantern, lighting up the whole room, will be harmless enough, the end of the long lantern where it comes upon the developing-table at one corner of the room being the only part to be careful about.

F. The way to exercise the care mentioned as desirable in the last paragraph is not to begin the development too close to the lantern window. Begin it three or four feet off, and, when the image is pretty well out, bring the developing dish to within two feet of the window, which should be (say) one foot high, with its lower edge touching the surface of the developing-table. By beginning with a fairly good screen, and paying attention to this matter of distance, which is of much more importance than small variations in the actinic absorption of the screen, it is astonishing in what a bright light it is possible to work. Monkhoven's plates are very good ones, yet I develope them habitually with safety in a brighter and cooler light than I ever saw in use in the days of the old collodion process. In the history of religions the gods of one age of thought became the devils of the next age, and in the photographic day now dawning the old ruby and red lights which Mr. Debenham has killed will be regarded as the exploded devils of the earlier photographers, and I believe that pure yellow and orange will go after them to the same limbo.

G. This proposition needs no defence. The first coloured screen has filtered out all the actinic rays it had the power to absorb, so a second one of the same material can do little more by its colour; consequently its presence, practically speaking, but darkens the room, and has little influence but that of injuring the eyesight of the operator.

H. This may be a point of temporary contention. Quite recently I stated that a doctor who threw red or yellow rays constantly upon the eyes of a man of weak vision would be considered mad; also, that if the fields and forests were of these hot colours we should all soon be blinded. Why then have them in the developing-room? It is true that the green rays are dangerously near to the blue in the spectrum, and that the blue must be sharply cut off for developing-room purposes. It is possible to find a screen composed of two sheets of different greens which would do this, and the right greens can be easily discovered by means of a polychromatic negative. But the yellows which will do this are more numerous, and altogether Mr. Debenham's selection of yellow *plus* green colours rests upon a sound scientific basis. His green is not the best he could have chosen. An intensely bright apple or sea green would be better. He can easily hit the best colours by the use of a polychromatic negative with tissue papers.

As a fact other operators than Mr. Debenham, few in number, have habitually used a more or less green light; but to him belongs the honour of having brought its utility, by his energetic public action, so very strongly before photographers, that its value can be no longer practically ignored, and the eyesight of large numbers of operators must thereby be preserved. He has favoured me with specimens of the materials he uses. The yellow is the element of safety; it is a thick paper, highly coloured, so has the advantages of the Starnes' lamp combined with fairly good absorption of the blue rays by colour. His green is altogether unsafe, but gives the cooling effect, and cuts off a few actinic rays which escape the yellow. An improvement would probably be to select a thick green paper, which green must be one of the few (I admit there are but few) greens which are tolerably safe, and to use very thin screens of bright yellow. His light will then be cooler. My light, from only two thicknesses of highly-coloured yellow and green specimens of the thinest tissue paper, is brighter than his, area for area, and probably if it were to be severely tested is not so safe. But what does that matter? Development six inches further from the lamp more than cancels all the difference, and this slight alteration of position of the developing dish is no great hardship.

A number of screens of *white* tissue paper will give the safety of the Starnes' lamp by their interior reflections and refractions; experiments might well be made in this direction. Each additional sheet means, in other language, but increasing the distance of a bare candle-flame from the plate.

Other experiments might be made with two magic lanterns by throwing two discs upon the screen so as to overlap each other, and placing a differently-coloured paper in each lantern. The result of mixing two *lights* is altogether different from the result of mixing two differently-coloured *paints*, and to an astonishing degree to those who have not tried it. In mixing paints red and blue make violet, yellow and blue make green, and so on, as everyone knows; but in mixing differently-coloured *lights* altogether different effects of colour are produced, and if Mr. Debenham does this at his forthcoming lecture to the London Photographic Society, he will be able to state and to show the actual colour of his light, which at the present moment he confesses himself unable to describe.

As the object of these lines of mine has been to save eyesight, the means of happiness and comfortable home to many a struggling brother of my craft, it may be well not to close this article without making their meaning perfectly clear for practical work to those who do not study the simplest scientific principles. I mean to those who offer "your likeness and a rasher of bacon for sixpence," and who, in the open air or otherwise, produce the old soot-and-whitewash likeness, embellished with comets and other astrological mysteries. These should go to the nearest shop where plenty of coloured tissue papers are sold, and select one very bright green and one very bright yellow—the colours so bright that they, unlike those of the other tissue papers, light up the faces of the persons turning over the various sheets of coloured papers in the shop. The brightest yellow and the brightest green being thus chosen, those two papers should be selected and pasted upon a cardboard lamp as its window, the light inside the lamp being then a common candle. So long as the operators *begin* their development (say) two yards from this lamp, and bring the plate nearer as the development approaches completion, I will answer for the safety of the development, and that they will be working in a brighter light than they have ever known before, if they have been ruining their eyes by the Debenham-killed dead-and-gone red glasses. If the colours thus bought chance to be very good they can work with safety even within but two feet of the light. A top and bottom to the lantern are worthless. The white light escaping beneath cannot get directly into the dish; the top light after reaching the ceiling and coming down again is practically harmless, in accordance with the law that the intensity of the light varies inversely with the square of the distance. These are the simplest instructions I am able to give without testing shop papers spectroscopically, or by means of a polychromatic negative. The latter method is infinitely the best for practical purposes.

Where is the manufacturer of the future who will first introduce into commerce a variety of intensely-stained green and yellow oil silks, more especially green? If I remember rightly, away here from books of reference, boiled linseed oil is the vehicle used in giving transparency to thin silks. If so, there should be no difficulty or expense in making coloured experimental specimens in a small way in the first instance. W. H. Harrison.

Lucerne, April 17, 1884.

ON THINGS IN GENERAL.

What a pleasure it is to see the familiar name of Hardwich in the Journal. It brings one back to the time when not only was no library complete without a copy of "Hardwich," but when it formed the only technical library of almost every photographer in the country. A quarter of a century has seen many changes brought about in photographic operations and processes, but I shall hold with almost affection to my early editions of Hardwich's *Photographic Chemistry*. The latest contribution of the reverend gentleman to the practical side of magic lantern work, so closely connected with photography, is very valuable, and, in connection with that by Mr. Lewis Wright, deserves most careful attention from those interested in such matters.

There are at the present time a large number of persons interested in lantern work—from the manufacturer who constructs the lantern to the exhibitor who uses it; but most of all is the photographer concerned, who bids fair to be almost the entire producer of, or at least intermediary in, the production of slides. The slides, too, are growing in value as an educational influence, from the scientific and accurate character of the diagrams and illustrations they exhibit; hence it is that the importance of taking every step to ensure safety during exhibitions becomes, if possible, intensified, and the experiments of the capable gentlemen I have named are of value. Few people but those who have had personal connection with the subject have any conception of the crass ignorance and the marvellous carelessness of some who use oxygen and hydrogen or ether for their lanterns. Safety-jets, if a real safety-jet could be devised, would be a great boon to nervous watchers; but a pseudo safety-jet would be worse than all. I once saw evidences of an accident that would exemplify my meaning—a room with the windows blown out and the ceiling damaged. A number of young men met for social improvement, and one cleverer than the rest got up some oxy-hydrogen experiments—mixed gases—a safety-jet of his own construction, an iron tube, some short lengths of wire packed in, and a big nail to tighten it. Of course there was an explosion, but, providentially, no harm was done to the assembled students beyond a terrible fright. I fervently hope that the practical outcome of the experiments initiated and the theories described will result in the invention of a jet which may really deserve the name of "safety."

Messrs. C. and J. Darker's polariscope exhibition was of a most interesting character, and the repetition of such lectures as that which accompanied it are calculated to be of great value. Photography has passed its period of babyhood now and requires real, intellectual food, of which the rising generation cannot too readily avail themselves. The race will be for the swift and the strong, and the combatants of the future will have to equip themselves with something far in advance of the mere dexterity acquired by practice if they are to take a forward position and its equivalent—high pecuniary recompense.

Science and art must be combined in one for the picture photographer; but mechanical and scientific photography is now of such importance that the artist will not always be needed. An interesting side light has been thrown on this phase of the subject from several quarters lately, and the ruling of Mr. Justice Miller, in the Supreme Court of the United States, in the Oscar Wilde copyright case, though on a technical law point, incidentally gives his views on this old "art" question. In the picture in question he held to be proved (the proof being an important link in the argument) the existence of those "facts of originality, of intellectual production, of thought and conception on the part of the author," which were more important to be proved in the case of copyright than in one of patent right.

By-the-bye, I am much obliged to the editor of the *St. Louis Photographer* for the flattering terms in which he speaks of me; but when he quotes from my lucubrations *verbatim* I should be glad if he would do so correctly. The March number of that capital journal contains what he terms "the following extract from 'Free Lance'"—a sentence that in its present form "Free Lance" most certainly never wrote. Something like it may be found in what I have written, but at present I do not at all remember writing anything like the paragraph quoted which I have just come across in the pages of the above journal.

Photography has afforded plenty of food for the lawyers of late, but I never felt greater satisfaction in reading law reports than I have lately when I see how a few disreputable scoundrels have been laid by the heels—how one man for publishing those loathsome abuses of our art which, at all risks, are still perpetrated gets a long term of imprisonment; how another for theft committed while receiving the courteous and kind treatment of his victim is given some time for enforced reflections upon optics in general and photographic lenses in particular; and how a land shark this time has actually been caught and made to disgorge. The more of such rogues and *canaille* there are punished the better will the ranks of photographers be for it; they can well bear some weeding out.

The Swansea case, in which the right to a negative was decided by the County Court Judge not to be vested in the client, is important. I believe there are far more of such cases occur in practice than ever come up for judicial arbitrament. The mere fact of such claims being made are a great annoyance; for the professional photographer in the daily discharge of his duty has, in the nature of his work, distractions and mental strain enough without being subjected to a gratuitous worry of this kind. Perhaps, however, such an important judgment as the one just referred to may help to nip in the bud many another attempt at a similar imposition.

I wonder what possible use can be found in quoting from the *New York Sun* a method of dissolving gum in "collodion and alcohol" for attaching false whiskers, and stating that the mixture, which dries immediately, can be removed by grease or spirits. The facts are as absurd as the recipe is futile.

I think Scotch photographers in general will not agree with Dr. Tulloch's dictum, given at a meeting of the Dundee and East of Scotland

Amateur Photographic Association, that "a gelatine negative rarely prints quite satisfactory without after-treatment," Dr. Tulloch being in the habit of using bichloride of mercury followed by ammonia to nearly all his negatives! I think he had better change his plate-maker, for gelatino-bromide would not be worth having if every negative had to be intensified. FREE LANCE.

A DAY ON "THE ISLAND."

PERHAPS there is no tract of land in the world which compresses into such a small space so many diversities of configuration as the Isle of Wight. It is a miniature of the great country from which it has been separated. There are moors and fells as bleak as those of Cumberland or the West Riding; chalk downs which recal Kent and Sussex; wooded undulating plains like those of Hampshire; and great stretches of rich arable land as fertile and as carefully cultivated as any in Leicestershire. Amid such a variety of scenery, with the sea continually presenting itself as a background, and historical reminiscences upon every side, the amateur would be hard to please indeed who did not find subjects enough to gratify his photographic propensities.

In these days of rain and tempest, when outdoor photography is at a discount, and the ever-vigilant eye of the Astronomer-Royal fails to detect a ray of sunshine for weeks on end, there is a pleasure in recalling past campaigns with the camera, and hunting out from some secluded drawer batches of old prints of valley, fell, torrent, and roadside inn, everyone of which recals some pleasant companion or enjoyable excursion. But more profitable than these musings over bygone days is the pleasure of mapping out operations for the future. There must be many who are making preparations for the bright spring weather which will shortly be upon us, and to such a short sketch which may direct their attention to "fresh fields and pastures new" must be of interest. Let me endeavour, then, to give a brief description of what may be done within the limits of one day upon "The Island," as it is proudly called by its inhabitants, to the exclusion of all other islands upon the surface of the globe.

To my friend Johnson, of London, the path to the Isle of Wight lies through the Waterloo Station. Behold him there at an early hour of the morning, clad in a fearful and wonderful Ulster, and the slouched hat dear to the artistic and Bohemian mind. No need to inquire the object of his mission, for under his arm is his folded stand, and in his one hand he bears the most compressible of cameras, while the other is occupied with a handy deal box containing plates and necessaries. Johnson goes through the formality of paying fifteen shillings and receiving a return ticket to Ryde in exchange; and then, with a feeling that come what may his retreat is secured, is whirled off in a third-class carriage.

The journey to Portsmouth occupies about two hours and a-half, and the traveller is eventually deposited upon the harbour pier, alongside which the fine, roomy "Victoria" is snorting impatiently out of its two funnels, and in full readiness for its short voyage. There the doctor, with apparatus corded and strapped, has been stamping up and down for a-quarter of an hour waiting for the London train.

From the quarter-deck of the "Victoria" a magnificent view of the harbour was to be obtained. There was a-quarter of an hour yet before the steamer could get the baggage aboard, and our photographers spied their opportunity. There was a clattering of straps, a turning of keys, a fitting of joints, and two uncouth three-legged, one-eyed creatures sprang into being. It was one of those bright, breezy mornings on which mere existence is a pleasure, and which gladden the heart of the photographer. A few bystanders gather curiously round, but the operators are imperturbable. The carrier is slipped in, the slide is slipped out, the shortest of exposures allowed, and the deed is done. Surely a more interesting view was never committed to gelatine. In the foreground lie three great three-deckers—the "Victory" (the old historical flagship of Nelson), the "Duke of Wellington," and the "St. Vincent." Beside these great floating monsters is moored a tiny gunboat—a representative of the modern tendency of naval architecture as compared with the ancient. By the side of its companions it looks like a duckling among swans; yet in its very insignificance lies its strength, since it offers no target for an enemy's shot. Around and between these vessels a swarm of steam launches, yachts, and shore boats fill in the scene, while behind it all the quaint little town of Gosport lines the water's edge and forms a background to the picture. Both plates were complete successes, giving as good an idea of the effect as can be produced without the blue of the sea, the grey of the houses, and the fluttering, coloured pennons of the men-of-war, with the artistic dash of brilliant scarlet from the coats of the marines upon the quarter-decks.

And now the good ship "Victoria" gives a final snort of expostulation, and churns up the water impatiently with her paddles. "All aboard!" shouts the captain. The warps are thrown off, and the vessel steams slowly out of the harbour, passing under frowning batteries, where the black-mouthed cannon peep sullenly out, as though sulky at having no more honourable task than the firing of salutes for so many hundreds of years. The channel here seems to the uninitiated to lie dangerously near the shore, even the largest ships passing within a stone's throw of the beach. There is a story, indeed, that on the occasion of some great wooden man-of-war going out in the beginning of the century she ran her bowsprit through the coffee-room window of the Blue Posts Hotel, considerably to the astonishment of some gentlemen who were dining therein. How far this is legendary and how far true is for some local historian to decide.

After touching at Southsea Pier the steamer stood right across for "the Island." Finer views could hardly be obtained than those of receding Southsea, with its charming variety of colour, white and red alternating in the houses, and the long line of shingle with the waves breaking merrily against it, or of the approaching shores of the Isle of Wight, with its undulating wooded hills, and the towers of Osborne peeping above the trees on the extreme right. Both were transferred to the plates of the photographers, together with a beautiful seascape of the Solent, with a solitary man-of-war lying at anchor at Spithead, and the three marine forts which stand out of the water like so many gigantic cheese-boxes, and command the winding channel which leads to the harbour. As the light was somewhat glaring the sky-shade was used in taking these views.

The Solent is five miles broad between Portsmouth and Ryde, so that twenty-five minutes of steaming brings the travellers across. Johnson's train has landed him on the pier at ten o'clock, and it is now hardly eleven, so that our excursionists have still a long day before them. Ryde pier is a very long one. As Johnson remarked, if it were a little longer there would be no need for any steamers at all. Happily there is a steam tramway which runs down it, and saves the necessity of trudging over half-a-mile of planking. The town itself is a decidedly hilly one. It is not so steep as the side of a house, but considerably more so than the roof. If you slip anywhere within half-a-mile or so you run a chance of reaching the beach in a shorter time than ever you took to traverse the same distance before. This is when you do not happen to bump into an inhabitant. In that case it is the inhabitant who gyrates down to the shore. If balloons were substituted for cabs in this town it would allow some small degree of comfort during the short time which will elapse before the whole thing goes adrift and slides majestically into the sea. I could say several ill-natured things of Ryde, but I refrain. A sense of my duty to the public, however, compels me to warn all future photographic travellers against every form of spirits in the island; for malignancy and venom they transcend anything I have ever imbibed, except, perhaps, the trade rum of Africa, which, drunk raw out of a broken cocoa-nut shell, tastes like a torch-light procession.

To follow our travellers, however: the first move after getting into the town of Ryde is to repair to a large horse-and-trap agency there, and to engage an open carriage for the day—a matter which is not a very expensive one. Thus provided, the whole island is at their command. Should their taste lie in the direction of Royalty, it is but six miles from the palace, where there are many beautiful views to be had; and just beyond lies the quaint old town of Cowes, with the many studies of the finest yachts in England which can be obtained there. If, however, the artist be of a historical and archæological turn, then he should wend his way to the little town of Newport, the capital of the island, where, besides its many inherent beauties, there is the opportunity of viewing and photographing the venerable castle of Carisbrooke, in which Charles I. was imprisoned before being taken to London and tried by the Parliament.

To confine myself to actual facts, however, the travellers, after a council of war with their driver, decided upon a somewhat more ambitious scheme than either of those indicated above. This was to drive right across the island, after first inspecting the Roman antiquities which have been lately unearthed at Brading. Brading is about four miles from Ryde, and as the road runs along the hills overlooking the sea the view was a beautiful one. Twice was the Doctor tempted out of the carriage and twice did splendid seascapes reward him; while Johnson, more improvident of plates and less accustomed to such scenery, excited the slumbering wrath of the driver by a long series of stoppages at the most inconvenient places—a wrath which showed itself in many mutterings and shruggings of shoulders, and was only eventually washed away by copious offerings of beer.

Brading is a pleasant little spot, and derives its principal importance from the magnificent specimen of a Roman villa which has been dug up in the immediate vicinity. From a short distance this interesting relic looks more like a quarry than anything else; and, alas! the operations of the photographer are confined to a distance, since the picturing of the tesselated pavement and other remains are a monopoly which the vagrant artist is not allowed to infringe upon. The tourists had to content themselves, therefore, with this general treatment of the subject, and then, after being divorced from their cameras, were led through the different chambers by a remorseless guide who explained the habits and customs of the "hancient Romans" in a manner which was more amusing than trustworthy.

The road from Brading leads to Newport, but there is a side road which opens into the highway between Ryde and Ventnor, and this was selected by the driver. This main road, which runs from north to south across the island, passes over a succession of undulating hills, from the summit of every one of which a magnificent view is to be obtained. Curious features in the scenery are the numerous monoliths—long perpendicular stones erected upon the summits of hills, either as landmarks or for some other purpose. These abound in the Isle of Wight. A succession of little villages were passed through on the way, offering as fine a selection of rural "bits" as could be found anywhere—the little wayside cottage with thatched roof, diamond-paned windows, and clematis or Virginia creeper fringing the doorway; or, perhaps, the grizzled, round-shouldered proprietor, with his black pipe in his mouth, sitting "*sub tegmine fagi*," densely unconscious that he is about to be endowed with a franchise, and that the press of the country are clamouring about his wrongs. There is often more interest in a little scene of this sort, selected artistically and well worked out, than in the broadest and most ambitious rendering of the beauties of nature.

Ventnor is about twelve miles from Ryde. As you plunge into the heart of the country the sea disappears entirely, and you might imagine yourself in one of the midland counties of England. About three miles from Ventnor there is a large inn on one side of the road and a wicket gate on the other. Here the coachman pulls up with decision. At first, knowing the habits and customs of coachmen, our travellers imagine the inn to be the reason of this peremptory halt; but the landlord quickly sets them right, and they learn that the wicket gate is the attraction. Passing through it, camera in hand, they pick their way down a winding path and then across a brawling torrent. From there the path runs down a thickly-wooded valley, the trees meeting overhead so as to hide the sky, and the stream gurgling among the bracken far beneath. This is the famous Shanklin Chine, and certainly a more beautiful or fairy-like scene could hardly be conceived. The Londoner did it justice, however, in the two plates which he expended over it—a proceeding very jealously watched by the custodian of the place, who derives his income largely from the sale of prints.

Leaving the Chine behind, the carriage rolled over a tolerably-level road a couple of miles in length, terminating in a steep hill, which was rather a pull for the tired horse. Up to this, as I have said, there were no signs of the sea, but on reaching the crest of the hill a wonderful view lay before the party. Almost directly beneath was the ocean, stretching right away in every direction to the horizon. Coming so unexpectedly I know of no view in the world which gives such an idea of an infinite expanse. Here and there one looks straight down on the deck of some steamer or sailing ship, ploughing across to St. Malo or tacking along to Southampton. They look like toy vessels—mere specks in the enormous stretch of water around them. It is needless to say that cameras were once more in requisition, and this magnificent seascape packed away in our plate-carriers.

When one leaves Ryde he fancies that he has seen the steepest town in the world, but his mind broadens when he comes to Ventnor. It is very much steeper, and gives the impression of being a little more than perpendicular. It is the fact of being built on the side of this hill that gives the place its great reputation as a resort for consumptives. No wind but the balmy south one can get near it. Still there are drawbacks, and when a consumptive falls out of his front door down the High-street and into the sea his language is just as virulent as that of any healthy man.

Commend me to the "Crab and Lobster" Hotel at Ventnor. Its situation is charming, its fare excellent, and its charges moderate; or, at least, moderate for the island, which is never at any time an economical spot. At one of the open windows which line the elegant coffee-room, and through which the summer breeze wafts the perfume of many a flower unknown in higher latitudes, there sat that day two pampered and enervated photographers who had solemnly packed away their cameras and delivered their whole minds up to the one idea of a comfortable dinner with a soothing pipe to follow. After all they had a right then to indulge in a little *dolce far niente*, since they had accumulated a finer variety of picturesque effects and interesting views than could have been taken in a week in a less-favoured locality.

It was necessary for the Doctor to be back in Southsea by nightfall, and the Londoner was also determined to be back in town by the evening train, so that after a climb over the curious little town the carriage was discarded and the train taken back to Ryde. Here the six o'clock boat was caught, and by seven the professional man was among his patients, and his friend within two hours was striding once more along the platform at Waterloo—a poorer man by some two pounds, but a richer one by the varied assortment of artistic pictures which he bore in his little deal box, as well as by the store of iodine and ozone which had renovated his lungs and oxidised the carbon of London.

In this little sketch I have simply attempted to give some idea of the pleasure and instruction which may be compressed into a single day by dint of a little energy and enterprise. A few such excursions during the summer months would, without being any great drag upon his purse, teach the Londoner the beauties of his own native land, and furnish him with a splendid series of pictures. If there be any one of my readers whose attention is drawn by this short article to the magnificent field for outdoor work presented by the Isle of Wight, then I have not written in vain. A. C. Doyle, M.B., C.M.

,, 1	Yorkshire College	College, Cookridge-street.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the technical meeting of this Society, held on the 22nd instant, Mr. W. Bedford occupied the chair.

Mr. W. F. Donkin showed two platinotype prints of the same subject, by Dr. Huggins, made upon linen. One of the prints was mounted in the ordinary way, and the other was immersed in glycerine and set between two glasses. The last-mentioned print had a very rich appearance in the shadows, resembling in this respect an albumen print.

Mr. W. E. Debenham supposed that mounting behind a glass with gelatine would give the same appearance.

Mr. A. Cowan showed a contrivance for carrying dry plates. The box was of cardboard, and opened along one edge. It slid into a lid or outer case—the open edge first. In the box itself was a book with leaves of a pure white paper. The plates were placed between the leaves of the book, and could be easily taken out and replaced in the order of their exposure. The box occupied less space than one with grooves, being only two inches in thickness.

Mr. T. Bolas suggested that it would be better to have rims to the leaves of the plate book.

Mr. Donkin had had a tin plate box, with grooves, which only measured two and a-half inches in thickness.

Mr. W. Ackland considered metal objectionable.

The Chairman said that the discussion suggested a question:—What is the best method of packing plates?

Mr. W. England thought that the use of paper mats was best. Some paper, however, made marks. He had found this particularly the case with white Bristol board, while with a greyish paper there were no marks except occasionally with large plates.

Mr. Lyddell Sawyer then read a paper criticising the exhibits at the recent lantern exhibition of the Society, in the course of which he contended that there was too much mutual congratulation, when sincere, outspoken criticism would be more beneficial.

Mr. Bolas said Dr. Mayer, of Carlsburgh, had what might be considered a representative collection of slides for the lantern, and suggested that he should be requested to send a selection for exhibition at a future meeting of the Society.

The discussion turned upon the production of warm tones in lantern slides.

Captain Abney said that Colonel Wortley and Mr. Cooper were among the first to achieve this upon bromide plates.

The colour of Mr. Wellington's exhibits being referred to,

Mr. Cowan said that for the warm colours Mr. Wellington had given very long exposure. He (Mr. Cowan) had given as much as 280 times the proper exposure, and brought out a good transparency by using bromide as a restrainer, sixteen grains to the ounce, in the ferrous-citro-oxalate developer.

Mr. Peek said that he had developed a plate with oxalate and found it under-exposed. He had afterwards treated it with warm water, and obtained a relief which did not appear to be under-exposed.

Mr. Cowan had tried Mr. Warnerke's method of washing away the gelatine, as in the carbon process. In one case he had exposed through the back of the glass, and after development had used water sufficiently hot to wash away the whole of the gelatine; but a powdery positive image was left upon the glass.

Captain Abney said that exposure through the glass would not answer with Warnerke's process. The development must be upon the surface that had been exposed.

Mr. Bolas inquired whether Mr. Peek had tried inking the plate which he had treated as described, and, if so, whether it was capable of yielding a good transfer.

Mr. Peek replied that he had, and that a good transfer did esult.

Mr. Bolas considered that in that case it should prove a valuable process.

The meeting was shortly afterwards adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society held on Thursday, the 17th instant, the chair was occupied by Mr. W. K. Burton.

The Chairman, in calling upon Mr. Debenham to deliver a lecture on lenses, said that the subject was one requiring great exactness, and the lecturer from the strict accuracy of his writings was particularly qualified to deal with it.

Mr. W. E. Debenham then delivered his lecture *On Lenses* [see page 263], illustrating his remarks by a large collection of lenses, by diagrams, and by photographs produced with some of the instruments under consideration. At the conclusion of the lecture,

The Chairman said that Mr. Debenham had kept clear both of the Scylla of inaccurate and slovenly statement and the Charybdis of those horrible-looking mathematical formulæ which were quite unintelligible to photographers generally. As a means of ascertaining the equivalent focus of a lens the following method was the one which he had found the most convenient:—From his window a row of electric lamps was visible. Of these he focussed two distant ones upon the ground glass of the camera. He then marked the points which they occupied, unscrewed the lenses from the mount, and in place of the diaphragm inserted a piece of card having a pinhole aperture. The camera was then racked until the images of the lamps occupied the same places that they had done when using the lens. The distance of the pinhole from the ground glass was the equivalent focus of the lens. Any bright distant lights would serve instead of electric lamps, but they must be distant. On the importance of flatness of field he quite agreed with Mr. Debenham. He had seen one of our leading opticians, when examining lenses, satisfy himself that the correction for central definition was perfect, without considering the requirements of photographers that that definition was required to be upon a flat surface. As to the diffusion-of-focus system applied to lenses: that was due to Mr. J. Traill Taylor, who some time previous to the advent of Mr. Dallmeyer's lens had read a paper upon the su ject before an Edinburgh society. With respect to the varieties of single lenses: he had compared two—one the wide-angle landscape lens, and the other a lens of the old type made by Mr. A. Ross. He had been surprised to find that with the old lens he could get a certain definition with a larger diaphragm than with the other, and by placing the diaphragm near the lens could cover as large a field. Finally: he would endorse Mr. Debenham's advice to use the central and flattest part of the field only—a narrow angle that is—whenever the subject permitted of it. He thought it would be generally admitted that the best focal length was two or three times the length of the picture.

Mr. J. T. Taylor, referring to the difficulty of getting flatness of field with a large aperture, showed by a diagram on the black board Professor Piazzi Smyth's method of overcoming this difficulty by means of an additional lens close to the plate. This lens had a flat surface next the plate, and a concave one in front of the same radius as the focus of the lens used in forming the image. The image was thus received upon its concave surface and transmitted to the flat surface of the plate behind. This arrangement was not to be considered as forming part of the lens itself, but was an addendum to it. He thought that the photographic lens of the future would in all probability be constructed on the principle of the orthoscopic or dialytic lens—that is, one having a concave posterior element like the lens which Petzval had for a time laid aside. Referring to American lenses Mr. Taylor said that several years ago Mr. Morrison, of New York, had constructed lenses giving similar results to the non-distorting wide-angle. He had also constructed rapid group and copying lenses, for which claims were made similar to those of the European "rapid" or Steinheil aplanatic class. These were corrected in a different manner from those just referred to; but doublets of Ross and Dallmeyer had the advantage of being more easily constructed and, therefore, cheaper. The general form of these lenses resembled some described by Sir J. F. W. Herschel in The British Journal of Photography in 1861, and it was interesting to know that among the various diagrams then published was also one similar to the system more recently adopted by Mr. Dallmeyer as the back of his patented portrait lens.

Mr. J. Cadett remarked that he had gone through a course of mathematical optics without it being of much benefit to him, and he adopted the advice of Mr. L. Warnerke, who was a good mathematician and had studied the subject—"put the lens on to a camera and take a photograph, then judge from the result." What was wanted was a practical work on the subject, giving reasons for the particular curves employed, the nature of the compromises that were made, and the effect of deviation in particular directions from the specified details. As Mr. Debenham had once said—"Optics is not a matter of opinion, but of mathematical proof."

Mr. A. L. Henderson said that he had worked with an additional lens hung on to the back of a portrait combination, and would like an explanation of the effect which that produced. He also inquired whether the contact surfaces of a lens might not with advantage be vitrified together instead of being cemented with Canada balsam.

Mr. Debenham had not investigated such an extraordinary case as the addition of a lens not centered with the other lenses. As to vitrification he could see no advantage in it, and the lenses would probably be deformed in the process.

Mr. J. Barker said that he had two lenses of the same focus but of different diameter. On using the same sized stop in each, the one of large diameter worked nearly twice as fast as the other. He found that by the addition of a spectacle lens to an ordinary instrument it would work very well, although with an altered focus. This allowed of the number of lenses required of different foci being reduced.

Mr. A. Cowan's experience did not coincide with Mr. Barker's as to the difference of speed amongst lenses of equal aperture and foci. He had for experiment taken photographs with lenses of the most opposite type, but found that when stopped down in the same ratio no difference could be detected in their rapidity.

Mr. A. Mackie said that Mr. Debenham's able and lucid lecture would have shown how important it was to know something about the instruments we use. For ascertaining the equivalent focus of a lens he always employed the method described by the lecturer, and found it simple and satisfactory.

Mr. W. Coles inquired whether, in estimating the rapidity of lenses, account had been taken of the difference between using them at different distances from the subject.

Mr. A. Haddon said that the Society had amongst its members some who had studied the subject of photographic lenses. Would it not be possible to form a committee of lens grinders? Many made their own plates, and some certainly would like to make their own lenses.

Mr. Debenham, replying to the Chairman, said that he had used the Grubb single lens in portraiture with an opening No. 12, answering to $\frac{f}{4}$. As to the slowness of the smaller lens, mentioned by Mr. Barker, that might, to some extent, be accounted for with respect to marginal rays if the lenses were set far apart, but not for central rays. With a rather large stop, for all rays not central or nearly so, the amount of light which might otherwise pass through would be reduced by the lens appearing cut off at the sides. If there were thought to be any more difference in speed than could thus be accounted for, he would like to examine the two lenses referred to. As to the difference of exposure required according to distance, there were two elements in that. One which could not be calculated was the veiling of the shadows by haze, equivalent to what was called auxiliary exposure. With objects of the same class within ordinary limits, the difference of speed due to the lens being used at a longer focus for near objects was small and would not be likely to mislead the operator. For copying or other work, when exceptional proportions had to be obtained the distance would have to be taken into account.

On the motion of the Chairman, seconded by Mr. Haddon, the usual vote of thanks was accorded to Mr. Debenham. The next lecture will be on *The Science of Polarised Light*, by Mr. C. Darker, and will be given on the 8th of May.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

On Wednesday, the 2nd instant, this Society held its monthly meeting at 181, Aldersgate-street. The minutes of the previous meeting were read and confirmed. Mr. J. R. Nisbett and Mr. J. F. Lattimer were proposed and elected members of the Association.

Attention was called to a paragraph in the *Photographic News*, of the 14th ult., suggesting that paid canvassers should be engaged. The matter received the consideration of the Board, but no action was taken.

The other business having been dealt with, the meeting was adjourned until May 7th, at eight o'clock.

PHOTOGRAPHIC SOCIETY OF IRELAND.

The usual monthly meeting of this Society was held on Friday last, the 18th instant, in the Royal College of Science, Stephen's Green,—Mr. Thomas Mayne in the chair.

The minutes of the previous meeting having been read and confirmed, Dr. Robert Brown and Mr. James Robinson were elected members.

The Chairman then called on Mr. C. W. Watson for a communication, entitled *Retrospect*. In his remarks,

Mr. Watson gave a short *résumé* of photography from its earliest stages, tracing out the various improvements that had from time to time taken place up to the present period. Mr. Watson's paper was most interesting, and elicited a well-sustained debate.

Mr. J. V. Robinson gave some valuable information on the various methods of enamelling. In his hands the process of coating a previously chemically-cleaned sheet of glass with collodion, then applying a coat of best negative varnish, over that a thin layer of gelatine, and lastly pressing the print on the same and squeegeeing the air-bubbles out, had worked the best. The enamel proved tougher, the surface of the collodion apparently not being so easily damaged as when the application of varnish was omitted.

Dr. Scott exhibited and explained a very simple and ingenious form of actinometer which he had made. He had taken two pieces of sensitised albumenised paper and exposed one to the action of light for thirty seconds and the other for one minute. The colours thus procured were then accurately imitated on a piece of glass. The *modus operandi* was as follows:—When an exposure is to be made in the camera take out a small piece of paper and expose it until one or other of the colours has been obtained, noting the time necessary to secure the change. The paper thus acted as a standard. He (Dr. Scott) had tried this on several occasions and had never found it to fail.

Mr. J. V. Robinson exhibited a whole-plate camera made by himself, also a new camera-stand, the chief merit of which was the method of shortening the legs, the bottom or single lath sliding between the two upper laths and being clamped by a band of brass.

Mr. Watson also exhibited a new $7\frac{1}{2} \times 5$ camera. The various movements, as also the method of extending the base-boards, attracted a considerable amount of interest.

The next and last meeting for the present session will be held on Friday, May 9th.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

The twelfth general meeting of the session was held in the Religious Institution Rooms on Thursday, the 10th instant,—Councillor Robertson, President, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. Wm. Lang, Jun., then read an interesting paper on *Poitevin's Photo-Reliefs* [*ante* page 249] and showed a number of very fine specimens of work, which were much admired and freely criticised.

The Chairman in a few words thanked Mr. Lang for the great trouble he had been at in getting up the paper and illustrations.

The next business was the nomination of office-bearers for the ensuing session to be elected at the next meeting.

Mr. McGhie exhibited a number of magic lantern and window transparencies printed by contact on Cowan's gelatino-chloride dry plates. He (Mr. McGhie) said the process was exceedingly simple. The specimens before the meeting were the first experiments he had made with the plates, and they were very satisfactory in every respect. In his experience he had found magnesium to be the most satisfactory light for printing with. One and a-half inch of ribbon burnt seven inches from the frame was sufficient exposure for an ordinary negative. He also showed a new combined shutter and sky-shade by Guerry. The shutter had two flaps, one of which covered the sky for a certain part of the exposure, which time is regulated by a little lever.

The meeting terminated with votes of thanks to Mr. McGhie and the Chairman.

NOTTS. PHOTOGRAPHIC ASSOCIATION.

A meeting, consisting of a number of gentlemen interested in the art of photography, was convened on Friday evening last, the 18th instant, at the Corn Exchange, Nottingham. Amongst others present we noticed the following:—Messrs. Bourne, Geo. Shepperley, A. Cox, Byron, Carnell, Sands, Dodds, Donahay, Inger, Taylor, &c. The meeting was well attended by amateur and professional photographers, and the interest exhibited proved beyond doubt the willingness to co-operate in this direction to make the Association a success. Mr. George Shepperley occupied the chair, and at the close of the meeting over thirty members were enrolled.

The Chairman commenced his remarks by observing that some twenty-three or twenty-four years had been allowed to elapse since Nottingham possessed any organisation for the encouragement and support of photographic art; and, as almost all towns in the kingdom of any magnitude furnished opportunities to stimulate and foster experiment and research in this direction, it had long been a subject of general surprise that they should lack such advantages. He pointed out how in the leading London societies members of the profession with well-known reputations for skill attended regularly the monthly meetings and demonstrated by illustration and experiment the various new processes and apparatus. He alluded to the opportunities offered to art-students by the existence of the Art Museum School of Art and instruction at the Town University, and thought it anomalous that with these encouragements no such photographic association should have its existence in their midst. No occupation with which he was familiar was more pleasurable or fascinating than the pursuit of this subject when once preliminary details had been mastered. He hoped the large and influential gathering which he had the pleasure of addressing, representing as it did the principal professional and amateur talent of the town, was an augury of the probable permanent character of the association which they were then desirous of establishing. He called upon the gentlemen present to make themselves thorough and practical in their attendance, and he had then no doubt whatever to the ultimate successful career of the Association. He (the Chairman) then called on Mr. Sands to address the meeting.

Mr. Cox followed with a promise of his co-operation in the undertaking.

Mr. Bourne, in the course of some remarks, promised the meeting he would submit the large collection of his own works to the members, and give them his personal support and assistance.

Other gentlemen spoke, after which the following officers were appointed to act:—*President:* Mr. G. Shepperley.—*Vice-President:* Mr. A Cox.—*Committee:* Messrs. Townsend, Torquet, Inger, Byron, Dodd, Collins, Bourne, Pendry, Stanley, and Spray.—*Treasurer:* Mr. H. Sands.—*Hon. Secretary:* Mr. W. Donahay, Hyson Green.

Mr. Wilson, supported by Mr. T. B. Dodd, Hon. Secretary, made a communication from the Naturalists' Society of their willingness to accept the Association as a section, meeting at the social guild and enjoying all their privileges, the Association having its own officers to transact business.

Mr. Byron proposed that the kind offer through the Hon. Secretary be allowed to stand over, and the meeting be adjourned till Friday, the 25th inst., at 8 p.m. This was seconded by Mr. Carnell, and carried.

A vote of thanks was then passed to the Naturalists' Society for their kind offer; and after a vote of thanks to the Chairman the meeting was brought to a close.

ST. HELENS ASSOCIATION FOR THE PURSUIT OF SCIENCE, LITERATURE, AND ART.

Photographic Section.

A meeting of this section was held on Wednesday, the 26th ult.,—Mr. Heather presiding.

The Chairman showed a transparency printed by exposing forty-five minutes to his ruby lamp. It was under-exposed, but enough to account for fog.

Mr. Brook exhibited an enlargement on Hutinet's gelatino-bromide paper, developed according to instructions and with the solutions recommended by M. Hutinet. This was admired very much.

Some members stated that they had a difficulty in getting the high lights clear.

Mr. Taylor thought this was due to poor solutions, as he got them quite clear when he used solutions made up from Hutinet's formula.

Mr. Sherlock showed a number of prints of ferns in natural colour.

The Chairman and Mr. J. J. Houghton exhibited a selection of lantern slides they had made.

A large number of prints by members were passed round for inspection.

Discussions on Cowan's plates, waxing photographs, photographing interiors, lantern slides, emulsions, mounting photographs, and photographing in natural colours closed the proceedings.

Correspondence.

AMATEUR PHOTOGRAPHIC SOCIETY OF MONTE VIDEO.

To the Editors.

Gentlemen,—I have great pleasure in announcing the formation of an amateur photographic society in this city—I believe the first of its class in South America.

Apart from the idea of stimulating the love of the art of photography, the Society intends to import apparatus, &c., to be sold to the members at a small profit, which proceeds will be placed to the fund destined to cover the expense of building a gallery fully fitted, and the acquirement of instruments, too costly for individual pockets, exclusively for the use of the members.

Please accept the most hearty thanks from the Society for the interest you so earnestly take in the progress of the art, and please, through the medium of your valued Journal, congratulate our fellow societies in the name of the Amateur Photographic Society of Monte Video, wishing them all a long life and a merry one.

The following are the officers of the Society:—*President:* Don Francisco Zas.—*Vice-President:* Don Federico Vidiella.—*Treasurer:* Don William Lafone.—*Accountant:* Don Henry Elliott.—*Secretary:* Don Horace Ellis. (All honorary.)—I am, yours, &c., Horace Ellis.

Monte Video, March 25, 1884.

A RECLAMATION.

To the Editors.

Gentlemen,—In your review last week of *A Popular Treatise of Modern Photography*, exception is taken to a statement on the title-page, and attention is called to some inaccuracies, presumably arising from imperfect revision of the proof sheets.

In justice to myself I desire it to be clearly understood that my connection with the work extends only as far as page 53. I had nothing to do either with the contents of the title-page or with selecting the printed matter after the above-named page.—I am, yours, &c.,

George Dawson, M.A., Ph.D.

Notes and Queries.

"Will you please give me a good recipe for blackening the inside of the dark slide, both for wood parts and metal?—W. A. K."——In reply: Mix with ordinary negative varnish or lacquer a sufficient quantity of lamp black or vegetable black to impart a dead black colour, and apply it by means of a brush. This answers for both wood and metal; but for the latter heat ought to be applied in order to make the varnish adhere properly.

J. G. inquires:—"1. To whom must I apply for a license to keep a still, and what will it cost?—2. Are all portrait lenses alike in definition that have the same aperture and equivalent focus if made by two different makers—one being sold at £6 6s., the other at £15 15s.?"——In reply: 1. Apply to the Excise. We do not know the cost.—2. Certainly not; but if formed of glass free from colour they will work with equal rapidity. The definition will depend upon the curves selected and the perfection of the workmanship.

Mr. F. Dugon, in the course of a rejoinder to Mr. Berryman, says that he is willing to take up the gauntlet thrown down by that gentleman; but he adds:—"There are several difficulties to be overcome. The first is as to finding a referee. Another difficulty is this: processes are published which in the hands of experts are good, but in the hands of others are total failures. Your correspondent will oblige by suggesting how these difficulties are to be surmounted."

Mr. A. L. Henderson, writing *apropos* of the enamel topic now being mentioned in our *Notes and Queries*, says:—"I hope J. Berryman is not one of the many who, when they fail, when trying any particular process or formula, believe that something important has been kept back and 'misleading remarks made,' especially as far as my process is concerned. If J. Berryman will give full details about the misleadings of others he will confer a favour—at least on myself."

B. F., writing on the subject of photo-enamels, expresses a hope that Mr. Berryman will give a practical article on the subject. Referring to Mr. Dugon's success, as alleged by himself, he thinks it is scarcely ingenuous in him, a relative of and assistant to a well-known skilful photo-enameller, to allow it to be inferred that such knowledge as he may possess is the result of having "witnessed a free demonstration of an enamel process," and of his having succeeded fairly well in his very first attempt—presumably in consequence of such demonstration.——In reply: Granting the high vantage ground occupied by Mr. F. Dugon in this connection, still we do not see anything at all improbable in anyone being able to produce these charming little photographs, with more or less success, after reading the various articles which have appeared on the subject and then witnessing the process of burning-in the picture.

In a communication, dated April 19th, "S. T. W." says:—"In your issue for yesterday you give a formula for a rapid emulsion, contributed by 'Ajax.' As I am but a beginner in emulsion-making I am rather puzzled to know whether 'Ajax' means that the emulsion is to be melted in the solution of glycerine, alcohol, and thymol prior to coating, or whether the cake of emulsion is to be taken out and melted with the addition of water. If the latter, what quantity of water must be used? If you would favour me with this information in your column of *Notes and Queries* you will very greatly oblige."——In reply: We imagine the cake of emulsion is simply to be immersed, not melted, in the glycerine-alcohol solution. Perhaps "Ajax" will supply an answer.

"SEGELOCUM" (Lincoln) writes:—"A new album of views of this city, similar to the albums published by Rock Brothers, has just been brought out by a local stationer, who has, without my permission, copied several of my newest and best photographs. The pictures are cabinet size—litho. copies *traced* direct from the photographs, and copied as nearly as possible. I wish to know if I have any possible chance of redress, or if I can protect myself in any way. The photographs were not copyright, but I am informed that I could stop any further production of the views. Is it *imperative* that a photograph shall be registered *prior* to the sale of the same?"——In reply: There is, in our opinion, no chance of our correspondent obtaining any redress for what has been done. We base this opinion on the second clause of the Fine Art Copyright Act of July, 1862, in which it is stated that "Nothing herein contained shall prejudice the right of any person to copy or use any work in which there shall be no copyright." The inference from this is, we think, that if a photographer do not protect himself by obtaining copyright in his productions any person is at perfect liberty to copy them. Such protection must be secured previous to the issuing of a single copy; that is imperative. But whether obtaining copyright for the pictures, now that there has been acknowledged copying of them, will act retrospectively we are not only by no means certain, but have a strong conviction that it will *not* do so. And, not only so, but registration *now* will only, at best, act prospectively in the sense of preventing further copies being made from such picture without having power to stop the issue of those made previous to registration. No action can be brought on account of pictures issued previously. In this respect the law of copyright as regards books is quite different from that relating to photographs. In respect to books: registration need not be made until the morning of the day on which an action for infringement or piracy is to be tried; but this registration, although effected at the eleventh hour, acts retrospectively. While such is our opinion with regard to this imperfectly-understood question, we would be glad to be favoured with that of others, especially of any who have what we may term an "experimental acquaintance" with the subject.

Exchange Column.

☞ Several "Exchanges" are crowded out till our next issue.

S. WELLS (Goole).—Your notice is virtually an advertisement, and cannot be inserted in this column.

I will exchange Shew's gem camera, with four lenses, for outdoor camera or large view lens.—Address, D., 2, York-street, Covent-garden, London.

I will exchange a duplicate set of THE BRITISH JOURNAL OF PHOTOGRAPHY for the last four years for years previous to 1874 of either JOURNAL or *News*, or any one year for the *News* of 1880; also a large quantity of duplicate numbers to exchange for others; want to make up set.—Address, W. E. DEBENHAM, Massingham House, Haverstock-hill, London.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHS REGISTERED.—

William Hudson, 62, High-street, Bordesley, Birmingham.—*Four Photographs of the Misses Ormond.*

Edmund Eccles, Broad-street, Bury, Lancashire.—*Three Photographs of the Rev. E. J. Smith, of Bury.*

William Watts, High-street, Staines.—*Photograph of Train Containing the Remains of the Duke of Albany.*

REV. FRANCIS JOHNSTON.—Received. In our next.

R. A. and two other correspondents this week have not enclosed their names and addresses; hence, according to our rule, their communications remain unanswered.

PORTRAIT LENS.—For the width of studio mentioned four feet opaque at each end will answer very well indeed. If the studio were wider five or six feet would possibly be better.

R. CRONIN.—Far too much pyrogallic acid has been employed in the development of the negatives. One-third the quantity in future will be quite sufficient. We shall at all times be happy to render you assistance.

A. B.—The change that takes place when crystals of sulphite of soda are exposed for a long time to the action of the atmosphere is that the sulphite is converted into the sulphate. No change is produced by light.

FREDK. W. MUNCEY AND S. A.—If the negatives treated with mercury are too thin they may be improved by treating them with a solution of Schlippe's salt; but if they are already too dense there is no satisfactory method of reducing them.

WM. LANG, JUN.—We are unaware if that particular modification of the collotype process is being practised, but we believe it is not. Those who employ collotype and kindred processes commercially are very reticent as to any information on the point.

BRADFORD.—You certainly should not condemn the paper because you fail to obtain rich purple tones upon it, if the negative you forward for criticism be a fair sample of those you are printing from. Such negatives will certainly not yield brilliant prints on any brand of paper.

E. MEARS.—The design for the shutter will do very well; but for very rapid exposures a smaller opening would, perhaps, be better. The sample of paper enclosed does not appear to be the "true" kind, but we have little doubt that it will answer the purpose quite as well.

PHOTO.—The spots appear to be due to very minute particles of some pernicious material getting into contact with them. If the prints had been mounted on cards printed in bronze powder we should be inclined to attribute them to that. Possibly particles of lime came in contact with them while they were drying or after they were mounted.

A TYRO.—The larger lens will do quite well for the small work, provided the camera will expand sufficiently long for focussing. Few half-plate cameras, of ordinary construction, will extend to sufficient length for a 10 × 8 inch lens. If, however, yours will do so there is no objection to its employment.

J. BATLEY.—For highly-finished carbon pictures on opal glass the kind of glass known as "dead smoothed pot opal" is the best. Egg-shell surface should not be employed for such pictures, notwithstanding it may be somewhat lower in price. The difference in the cost of the two kinds is but trifling as compared with the more artistic appearance obtained on the dead smooth surface.

Q. E. D.—1. Any ordinary water-colours are suitable for working up carbon enlargements on matt opal glass. You will, of course, have to match the colour to that of the picture, as there are different colours in "carbon" enlargements.—2. Opal pictures by the carbon process are certainly best unvarnished.—3. The colour may be obtained from Mr. W. E. Debenham, 158, Regent-street, W.

M. E. D.—The polished surface of the portion of print enclosed appears to have been produced by heavily rolling on a highly-polished plate. A highly-glazed surface may be obtained on unmounted photographs by squeegeeing them down on a plate of glass immediately on being taken from the washing water, and allowing them to dry upon the glass. When the prints are mounted the glazed surface will, of course, be destroyed.

H. J. G.—You certainly can recover the silver by the method you suggest, but what advantage will be gained? When you have the residue as a chloride it is much easier to deal with in recovering the metal than if it were in the form of sulphide. Where, then, is the advantage of dissolving the chloride residues in the hyposulphite of soda, and then precipitating them as sulphide, from which the metal is not so easily recovered?

ZENO.—Zinc vessels will certainly not do for containing the hyposulphite of soda in which to fix prints. It would be much better to procure earthenware dishes than attempt to employ any kind of metal. If your prints are small, and cost is an object with you, common brown earthenware baking-dishes may be employed. If the sizes you work are large, then you had better construct a wooden tray and coat it with paraffine wax. This will have no injurious action on pictures.

W. H. SIMS.—The common copperas of the oil-shops may be used for making the iron-developing solution for wet-plate work, provided it be tolerably pure. Many operators we know prefer it to the ordinary protosulphate of the chemist, as they find that the small proportion of persulphate from the oxidation of the crystals conduces to intensity and greater clearness of the shadows. The objection to the commoner article is that there is always a risk of its being contaminated with other salts. Being sold by the oilmen at such a very small price, little or no care is taken to preserve it from contamination.

RECEIVED.—*Practical Guide to Photography.* Marion and Co. In our next.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 30th inst., the subject for discussion will be—*On the Preparation of Lantern Slides.* This being a lantern night, members and visitors are invited to bring slides.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, to be held at the Society of Arts, John-street, Adelphi, on Thursday next, May 1st, at eight o'clock, Mr. Norman Macbeth, R.S.A., has kindly promised some *Notes on the Composition of a Picture*, when it is hoped that not only will the members attend to welcome this eminent artist, but also make use of their privilege to introduce a friend.——In consequence of the lamented decease of the President, the dinner announced for the 10th proximo has been definitely abandoned; but the subscription list remains open, the form the memorial will take remaining for the decision of the committee.

CANADIAN PHOTOGRAPHS.—We have received a number of interesting pictures of Canadian scenery and life by Messrs. Barraud Brothers, of Barrie, Ontario. As examples of photography they show that our Canadian brethren are fully alive to what constitutes good photographic work—as, indeed, we were prepared, in this instance, to expect, since we know that Mr. H. T. Barraud, on a recent visit to this country, laid himself out specially to discover all that was to be learnt in connection with photography. As specimens of Canadian scenery the pictures before us lead us to feel that we should be glad of the chance of being "out and about" with the camera in the same region.

LONDON GAZETTE, *Tuesday, April* 22, 1884.

ADJUDICATION.

ROBERT BANKS, 32, Victoria-street, and Rembrandt House, Alexandra-road, Manchester, and 7, Talbot-square, and South Pier, Blackpool, photographer. First meeting, April 29, at 11.30 a.m. at the Official Receiver's, Manchester.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1252. Vol. XXXI.—MAY 2, 1884.

MIXING EMULSIONS.

The question raised in Mr. W. K. Burton's article upon this subject is one of the very highest importance to all who manufacture emulsions, and one which, at the hands of amateur makers at least, has never yet received any great amount of attention. On this account alone, therefore, Mr. Burton's details of his experiments will be of value as forming a starting-point from which other experimentalists may work; and we have little doubt but that before very long this line of inquiry will have been subjected to a considerable amount of research.

With the results of Mr. Burton's experiments we entirely agree; but with some of his deductions therefrom we must, to a certain extent, disagree. Thus, so far as the result of a mixture of two emulsions is concerned, we have invariably found that the mixture partakes more of the character of the more rapid than of the slower of the two, even when the proportion of the former is comparatively small. The physical qualities of the mixture, however, will be found to vary very considerably with circumstances; but, as a rule, we have found that in mixing a rapid, thin emulsion with a slow and dense one in anything like equal proportions, the good qualities of both are retained in the mixture—that is to say, that there is no great falling off from the sensitiveness of the one or the vigour of the other in the combination.

This may at first sight appear a somewhat anomalous state of affairs; for, as we well know, a certain weight of ice melted in a given weight of water at a known temperature will produce a temperature which may be calculated with unvarying exactitude. A mean is, in fact, struck between the two. In the case of the mixture of two emulsions of different sensitiveness, however, it will be found upon second thoughts that the conditions are altogether different. If the sensitiveness of the molecules of silver bromide were an interchangeable quality which enabled it to average itself throughout the whole mass—if, that is to say, a molecule of highly-sensitive bromide coming in contact with a molecule that was but feebly so, could impart some of its excess of that quality to its slower brother, and so form two molecules of equal and moderate sensitiveness—then we should have the conditions present in the case of a mixture of ice and water or of water at two different temperatures. But we have yet to establish the fact that such a power exists in sensitive bromide of silver; indeed, it is evident from Mr. Burton's and other experiments that it does not exist.

If, on the other hand, we assume—as Mr. Burton seems inclined to do—that the insensitive bromide exists in the mixture as so much inert matter, we should have as a result of such mixture an emulsion possessing all the sensitiveness of the more rapid of its two constituents, but giving less density of image in consequence of the non-reduction of the slower molecules. But experiment does not prove this to be the case; for, as has been stated, the sensitiveness under these circumstances is slightly lowered, while the loss in density is so small in proportion to the attenuation of the layer of sensitive bromide that it is evident there is a screw loose somewhere in that theory.

Our own view may be briefly stated, namely, that there is no *real* loss of sensitiveness, and that the slow bromide is *not* present as inert matter. With regard to the first: the apparent falling off in the rapidity of the mixed emulsion is due rather to the decreased density of the image, visible more distinctly in the delicate gradations which are usually taken as the test of the degree of action. A similar effect is produced by merely diluting an emulsion (either of gelatine or collodion), when the thinner films will give images which are apparently less exposed than the others; but it is scarcely reasonable to imagine that the mere addition of water to a gelatine emulsion, or of ether or alcohol to a collodion emulsion, can lower the sensitiveness.

Turning to the question of the inertness or otherwise of the slow bromide: we may refer briefly to Captain Abney's experiments with double films made some years ago. That gentleman found that if a plate were coated with an extremely rapid (but thin) film of emulsion, then with an isolating layer of albumen, and, *after exposure*, was covered with a film of *slow* and *dense* emulsion (collodion being used in both cases), the image produced on developing the compound film exhibited the qualities of the latter emulsion as regards density, though the exposure was only such as sufficed for the more rapid film. But, most curiously, upon separating the two films of collodion each caused an image partaking of the physical characteristics of its particular emulsion—the one being thin, the other dense—and this in spite of the fact that the latter had *received no exposure to light*, but had had the reducing action transmitted to it second-hand.

Now, it is pretty evident, if such an action proceed in the case of two separate films, that it will proceed also in an emulsion or film in which molecules of exposed and unexposed silver bromide (or, what amounts to the same thing, molecules of widely-different sensitiveness) exist in far more intimate contact. In other words, that the impact of light which suffices to impress the more sensitive molecules may leave the less sensitive particles intact; but that the molecular disturbance set up by the developer in the sensitive molecules suffices to transmit the reducing action to the surrounding insensitive ones, which thus add their share to the general density of the impression.

It is, of course, not only possible, but probable, that the withdrawal of developing force which the reduction of the unimpressed molecules entails may cause a practical decrease in the sensitiveness of the impressed ones. Be this as it may, we think it is certain that even the most insensitive or actually-unimpressed bromide takes part in the formation of the image; and the theory or hypothesis we have sketched goes far to explain the discrepancies between theory and practice alluded to by Mr. Burton.

VIEWING LANTERN TRANSPARENCIES WITHOUT A LANTERN.

It is matter for regret that one cannot employ binocular vision in the examination of a transparency, such as a lantern slide, under circumstances involving a high degree of magnifying. Could this be effected, a very pleasant table instrument might result with which one could while away many an hour in looking at these attractive pictures, which would then be seen under conditions more favourable than, and with apparent dimensions quite as great, as when they are projected on a large screen for the benefit of the multitude, and when no time is afforded for studying any one or more special subjects in detail.

According to the optical conditions given by Mr. Robert H. Bow, C.E., when, twenty-one years ago, he submitted to the Edinburgh Photographic Society his table stand with lens and holders for use in the examination of transparencies, the lens, which ought to be of meniscus form, should have a focus not greatly exceeding the diameter of the picture that is to be examined, which would give a focus of about three and a-half inches for a lantern picture of the usual dimensions of three and a-quarter inches. The diameter of the lens employed by Mr. Bow was one and a-half inch, and a plate of ground glass was inserted at a distance behind the picture sufficient to ensure its being so far beyond the focus as to prevent the texture of the granulated surface from being seen.

But this instrument, elegant and useful as it might be made, unfortunately recognises the examination of the picture by one eye only. To render it applicable for both eyes Mr. Rowsell, the inventor of the graphoscope, introduced an instrument under the designation of the "photoscope," if we recollect aright, by which both eyes could be employed. It consisted of a wide tube having a large lens at one end, and at the other a receptacle for the pictures, these being erected upon a stand suitable for placing upon a table. This was imitated under various names both at home and abroad, one American *pseudo*-inventor paying it the compliment of applying for a patent for the "invention" in that country.

But all these tubular large-lens instruments are ineffective as contrasted with Bow's arrangement, on account of the feeble extent to which the pictures are enlarged. With the latter one forgets that he is looking at a small picture, because of its subtending such a large visual angle that the eye roams over its surface as if Nature herself were being viewed. One likes, however, to have the use of both eyes, and this cannot be done with the short-focus lens. With the tubular large-lens system both eyes, it is true, can be employed; but the amplification is so trifling as to fail in evoking feelings akin to those elicited by the other plan.

Desirous of combining in one instrument the advantages of both systems, we have constructed a piece of table apparatus which shows a lantern transparency under all the conditions for successful examination that can be dictated.

Having determined upon the adoption of four inches as the focus possessing the greatest general utility, we endeavoured to effect the intended purpose by combining together large lenses of a diameter not less than the intended focus, so as to give an image free from colour and able also to yield the requisite amount of displacement to ensure parallelism of the beams when entering each eye respectively. Eventually this end was attained by a combination of three lenses of four and a-half inches diameter; but as two of these were achromatic, one being uncorrected for colour, the great expense of such an optical arrangement for popular purposes may readily be conceived.

Reasoning upon the best methods by which the same effects could be secured by a smaller expenditure of optical means, and tracing by a diagram the path taken by the ray from the picture to the eye, it was easy to perceive that the conditions of displacement lay in a direction opposite to that required for the examination of stereoscopic pictures. Hence, by entirely reversing the positions of the prisms in a stereoscope, so that their thin edges were turned to the outside instead of the inside, the condition as regards displacement was satisfied, but the requirements of amplification were far from being so met in a corresponding degree.

We next obtained two achromatic lenses of four inches focus, and by mounting them so that the axes of the eyes should be outside of those of the lenses to a material extent, we obtained both displacement and magnifying power. But now another difficulty intervened. When the separation of the lenses was such as to cause the coalescence upon the retinæ of the single image thus transmitted by the pair of eyepieces the whole of the picture was not equally sharp. When, on the other hand, the lenses were so arranged as to give individual sharpness, the retinal coalescence was imperfect; besides, owing to the necessarily-small diameter of an achromatic lens of four inches focus, and the necessity for having the axes of the eyes very near to the margins of the lenses, the whole of the picture could not be properly seen.

To secure greater dimensions in the eyepiece we next employed two pairs of achromatics of plano-convex form, each being eight inches in focus. But still it was found necessary to separate these systems so far apart as to cause the eyes to look through a point much too near to their margins. Eventually, and as the result of many trials in order to secure the best effects, we have adopted eyepieces composed each of a plano-convex achromatic of eight inches focus, combined with a lenticular prism also of eight inches focus. This prism is one of the class so universally adopted as eyepieces for the well-known prismatic stereoscopes, and it is no small advantage in connection with them that they can be purchased at an exceedingly low price.

The manner in which these eyepieces are mounted is as follows:—The achromatic lenses—which, like the prisms, are of a class that can be purchased very cheaply, and are one inch and three-quarters in diameter—are mounted so that their centres are separated two and a-quarter inches, or a rather less distance apart than the width of the eyes, the point to be aimed at being the making of the axes of the eyes to fall a little to the outside of those of the lenses. The flat side of this lens is next to the eye. Now, immediately outside of it is placed the prism, but, as already hinted, it is made to take a position quite the opposite to that assumed in a stereoscope; for in an eyepiece of this description the thin edge must be to the outside instead of being inside, as in the other case mentioned. The body of the instrument is four inches in length, and at the end opposite to that in which the eyepieces are inserted is a groove capable of receiving a lantern slide-adapter of the class on which an improvement revolutionary in its scope was so cleverly effected by Mr. Alexander Cowan a few weeks ago, and for particulars of which we refer the reader to page 150, in our issue for March 7th last.

The arrangement above mentioned—namely, the combination eyepiece and the adapter—forms a system so perfect for employment in the examination of lantern transparencies as to induce us te believe that this mode of viewing them is greatly to be preferred to that of projection on a screen; although the fact that only one person can examine them at a time is necessarily a drawback to the enjoyment to be derived from such inspection.

Immediately outside of the aperture through which the light is admitted to the picture a plate of carefully-selected flashed opal glass is inserted. At first we experienced a little difficulty in obtaining opal glass of the requisite purity of colour, and in the interim provided a highly-satisfactory substitute in the form of an emulsion composed of clarified gelatine and oxide of zinc spread upon glass. This forms a fine, homogeneous backing to the picture, permitting the most delicate details to be plainly perceived. Either of these two backings is to be preferred to ground glass, no matter how smooth it may be, and even though it be so far removed from the picture as to be quite out of focus. If preferred, a plate of glass having bands of transparent colour painted across it may be inserted behind the backing glass; and we have secured some pleasing effects by placing thin and partly coloured gelatine films behind, mounted so as to give a warm or cold tone to the picture by the mere rotation of a roller in the manner of a window blind. We can also impart such effects as a natural colour to the sky while the foreground is green.

From the hints here given we hope that such readers as desire to utilise their lantern transparencies in an exceedingly pleasing manner, and at the same time provide a useful and pretty ornament for their parlour table, will, from a perusal of the foregoing description, be enabled to do so without any difficulty. We may state that the angular size to which the transparency is magnified assimilates to that apparent on a large screen upon which a picture is projected in the usual way by means of a lantern.

PURPLE TONES AND READY-SENSITISED PAPER.

It is well-known to every practical printer that the tone of the finished print is in a great measure dependent upon the character of the negative from which it is produced. This remark is not confined to silver printing alone, as it applies equally well, though, perhaps, in a minor degree, to all other processes of photographic printing.

Even in the carbon process it might well be supposed that, as the colouring matter is an actual pigment, all prints made upon any particular sample of paper must of necessity be alike, whatever the character of the negative employed. Such, however, is not the case; for, in practice, it is found that when two prints are made upon a given sample of paper—the one from a strong and vigorous negative, clear in the shadows, and the other from a feeble one, with the shadows somewhat veiled—these two prints will be so different in tone that it is difficult to conceive they were printed on the same kind of tissue. Now, although, as we have just said, the effect exercised by the character of the negative in influencing the tone in the resulting print is well understood by practical printers, the fact does not appear to be so well known to many amateurs, who, therefore, when they are unable to obtain the tones they desire, are inclined to condemn the paper, while in point of fact it is the negative itself which is in fault.

We have had palpable proof of this from the large number of letters we have received during the past few months—and are still receiving—from correspondents complaining of the difficulty, or the impossibility, of obtaining anything beyond reddish-brown tones on the ready-sensitised paper of commerce. It must not be assumed that we are for a moment defending many samples of this article now in the market; for we have experimented with some which it was quite impossible to tone beyond the red-brown stage without obtaining mealiness, however strong the negative might be. With some samples of ready-sensitised paper—and this is one of the complaints frequently made by the tyro—a purple tint is easily obtained in the toning bath if the negative be a strong one; but it entirely disappears in the fixing, leaving the print of a dirty brown colour, often very woolly in texture, and far less purple in tone than if it had been removed from the bath at an earlier stage.

Since the idea has gained currency that purple tones in all probability will prove more permanent than brown there appears to be a greater desire to obtain them, and this it is quite impossible to do on many of the ready-sensitised papers now in the market, notwithstanding that the negatives are of a suitable character to yield such tones on ordinary paper. This we have proved ourselves by procuring, and printing from, some collodion negatives of the old school, taken some twenty years or so ago, when clear shadows and very intense high lights were the order of the day. Although the prints, on the papers tried, bronzed strongly in the shadows, still it was quite impossible with most of the samples to reach a deep rich purple tone, which remained unchanged when the print was fixed, and, at the same time, be free from mealiness. Whereas, using the same negatives, with paper sensitised by ourselves, on a plain sixty-grain solution of nitrate of silver, no difficulty was experienced in obtaining any desired tone; indeed, with the lime toning bath a cold black was reached without any indication of mealiness whatever.

It may be well to mention, however, that some of the samples of our own sensitising toned much slower than others; and those which toned the slowest, as might be expected, were those which were the most highly albumenised. It is well known that the more highly albumenised the paper—whether ready sensitised or otherwise—the greater the difficulty there always is in obtaining purple or black tones. Therefore, when these tones are desired a paper should be selected on which the surface is less highly glazed. Unfortunately, lightly-albumenised paper is rarely to be met with nowadays, as all manufacturers appear to aim at getting the highest possible gloss.

The difficulty of obtaining purple tones with more highly albumenised paper will be readily understood when we consider that if the paper itself be salted and sensitised—as in plain paper printing—the tendency of it is to print and tone to a purple or black. Albumen, on the contrary, if sensitised by itself—say on a glass plate—will print red and cannot be toned to a dark colour. Now, it is very clear that if the albumen coating on the paper be thick—as it is coagulated by the silver while being sensitised—the solution scarcely reaches the paper at all, it being chiefly confined to the albumen or its surface. Whereas, if the paper have a thinner coating of albumen, the silver solution penetrates through it and soaks more or less deeply into the paper itself. Hence, with slightly albumenised paper, the image is partly in the paper, which is prone to yield purple or black tones, and partly in the albumen, which has a tendency to red. But with a very thick coating the image, as we have already said, is formed almost entirely in the albumen; hence, at least one great difficulty in obtaining anything beyond a brown tone on very highly albumenised paper.

Apart from the difficulty of the image being so much confined to the albumen, many of the ready-sensitised papers are difficult to tone, owing to the preparation they have undergone in order to confer upon them their keeping properties. The convenience of ready-sensitised paper, however, is so great—particularly to amateurs—that, notwithstanding all its shortcomings, it will continue to be as largely employed as heretofore. Therefore, we subjoin a practica hint or two which, if taken, will enable somewhat darker tones to be obtained with greater facility on certain samples.

All ready-sensitised papers are more or less acid, and acidity, in any form, is always antagonistic to rapidity in toning. Consequently, it will always be a good plan, after the free nitrate of silver is washed out of the prints, to immerse them for a few minutes in a dilute solution of common washing soda, or, indeed, of any alkali. By this treatment the acid is effectually eliminated and the toning greatly facilitated.

It may be remembered that, some time back, we directed attention to the advantage of the paper containing a certain amount of moisture at the time it is printed. What was then said with regard to paper of home preparation applies equally well, and perhaps with greater force, to ready-sensitised paper, which, as a rule, is kept as dry as possible in order to preserve its whiteness. It will, however, be found that if the sheets be suspended in a damp atmosphere (so that the paper becomes quite limp) a short time before it is printed, it will tone more readily and be a darker tint than if it were exposed in a crisp condition. On this subject we may possibly have something to say on a future occasion.

DARK-ROOM ILLUMINATON.

As from Mr. Starnes' letter in our present number he appeared to think we criticised him unfairly in our last, we propose to point out briefly where we consider him to be wrong in his deductions, leaving it to our readers, but more especially to Mr. Starnes himself, to form a final judgment.

First, as to his statement that "it is useless to use two or more thicknesses of ruby glass, because the light which has passed through one would pass through the other unchanged, and that the action of the second thickness would be to simply cut off the power of the light, and for this purpose ground glass or white tissue paper would answer equally well." If ruby glass were a true red—that is to say, if it passed only red rays—there might be some truth in the first portion of the assertion; but, as everyone knows, the so-called "ruby glass" passes not only red rays but also orange, yellow, green, blue, and even violet, in proportion to its density, and that a sample of moderate intensity which allows a considerable amount of green to pass will, if doubled, cut off the whole, or nearly the whole, of that colour. There is no gainsaying that, and therefore the light does not pass through the second thickness "unchanged," even in colour.

We speak now entirely of the colour question. But will Mr. Starnes or Mr. Harrison, to whom he refers, assert that the superposition of layer upon layer of coloured media will not alter the original colour of the transmitted rays? If so, we think they will see cause to alter their opinions. If "stained red" glass, or the more common "pot orange" or "yellow," as it is called, be taken of light tint and several thicknesses combined, the visual colour as well as the absorption spectra will be found to alter considerably. Again: if a saturated solution of chrome alum, *made with cold water*, be viewed by transmitted light in bulk—that is to say, with a considerable layer of liquid intervening between the eye and the light—the colour will be red. But in proportion as the solution is diluted or the thickness of the layer decreased it will gradually change to bluish-green. The most remarkable instance of this change of colour, however, is shown by a sample of green sheet gelatine given to us by Mr. W. B. Woodbury. This appears to the eye in a single thickness as a pure chrome green; but as the number of thicknesses is gradually increased the transmitted light passes through a number of changes until it reaches ruby.

It cannot, therefore, be said that the light transmitted by a coloured medium (not being a pure spectrum colour) passes unchanged in colour through a second thickness of the same medium; while, so far as the loss of light from the want of transparency of the medium is concerned, our simile of the tissue paper is directly applicable. We do not intend to enter into any argument as to whether "ground glass or white tissue paper would answer equally well"—that is, equally as well as doubling the ruby glass—as that is a question more readily settled by experiment than by controversy.

With regard to the superposition of two complementary colours to form white light: Mr. Starnes is evidently labouring under a confusion of ideas which we shall attempt to remove. The late Mr. W. Spottiswoode, in his popular lectures on *Light and Colour*, used to exhibit an experiment in which two spectra were thrown in juxtaposition upon the screen by passing the electric light through a couple of prisms. By means of diaphragms the whole of the rays were then cut off, with the exception of a small portion in each spectrum representing any two complementary colours. The two circles of coloured light were then brought nearer together on the screen until they overlapped, when the colours entirely disappeared from the formation of white light.

Here we have the two complementary colours added one to the other to form white light; but, supposing we could glaze a dark-room window with two glasses of *true* complementary colours, we should have a very different state of affairs. One glass will rob the white light of all the coloured rays but its own; the second will do the same; and, as each of the two suppresses *the only* rays that are transmitted by the other, total suppression or the safety of absolute darkness ensues. Mr. Starnes would do well to study the difference between the *plus* and *minus* signs, if we may so describe the case, and then state his views on the subject of a "safe white light" produced by filtering it through media such as he suggests. To quote from Mr. Starnes' letter: "it is unfortunate that" *he* "should make such a mistake as to say that" *white light* "was produced when glass screens were used." We thank him for the attempted correction; but, after the examples we have given, he will, we hope, see that it was needless.

Now, Mr. Harrison's suggestion of the use of two lanterns glazed with different-coloured glass, and also Mr. Starnes' own idea of applying the two colours to his reflecting lamp, set up a different condition of things; for the two colours are then working in conjunction with, and not against, one another, as when superposed. Moreover, if an ordinary dark-room window be glazed with (say) blue and orange glass by covering one half with each colour, the elements of white light would be transmitted into the room instead of all light being suppressed, as would be the case if the whole window were covered with both colours.

As respects the schoolboy experiments we mentioned, and to which Mr. Starnes wishes a text-book reference: we must confess that we, like himself, have never to our recollection found the phenomena referred to in any recognised "text-book." We do, however, recollect, in our own schoolboy days, executing certain cabalistic signs and figures in certain coloured inks, which said designs appeared in different guises when viewed through glasses of different colour in consequence of the suppression of portions of the design, the whole art and mystery of this ingenious and diverting pastime having been derived from a boy's "play-book" of the day, the name, author, and existence of which have passed away long since.

As to Mr. Starnes' theories we have nothing to say, as the object of this article is not controversial, but merely to show that we have not thoughtlessly nor unjustly criticised him. If any misunderstanding should still exist in his mind as to the matter specially referred to, we shall be glad to discuss them personally or by private correspondence, unless he can show that we are wrong in our views, when he shall have every opportunity of publicity.

STARCH, GUMS, AND OTHER MOUNTANTS.

The *Moniteur Scientifique* recently had in its pages an interesting paper, treating among other things of the absorbent properties of starch, acacia gum, tragacanth, &c., in a manner that will afford some instructive matter for photographic use. Gelatine and starch in some of their many forms are, for mounting prints, perhaps, the substances most in repute, or, at anyrate, in demand, though acacia gum is often used; and tragacanth—less employed of any—possesses capabilities that have not hitherto been duly appreciated.

At the present time there are so many complaints made about the irregular expansion of albumenised paper when damp that a demand arises for a mountant that shall not cause such expansion. This want is best met by the process of dry mounting described in these pages a few months ago; for it will be noted that the irregularity quite disappears when the print is thoroughly dry. We may, in passing, observe that this dry mounting, at least in principle, is by no means the novelty that some imagine. We saw prints being mounted by a similar means nearly a score of years ago at Mr. W. B. Woodbury's establishment at Brompton. Be that as it may, the method is most excellent, and, when possible to be employed, should be chosen before any other, if only to avoid the very large percentage of loss from prints too distorted to send out—an effect which, unfortunately, is only discovered after mounting and when a mount is spoiled.

When, however, dry mounting of this kind cannot be carried out, the next best method is one where the adhesive material employed does not expand the paper after being spread upon it. Leaving out of question such substances as caoutchouc dissolved in benzole, &c., there are left practically only those aqueous solutions which are miscible with alcohol. Acacia, as representative of the gums, does not allow this, as precipitation would ensue; but gelatinous substances, typified by glue or gelatine, when dissolved in water, admit when heated so large a proportion of spirit that the small residual amount of water is found not to produce any increase of dimensions in any direction in the print. A hot solution of good glue will bear a very large quantity of methylated spirit being added to it without causing precipitation; and the method of making this mountant is to continue the gradual addition of spirit till a permanent turbidity is just on the point of being produced. When the mixture cools it becomes like a solid mass—white, cream, or pale brown, according to the colour of the gelatine.

This mounting solution has been very largely made and used, and at one time was vended as a secret preparation; but we have long since described the mode of its manufacture. We must here point out the necessity for employing a pure sample of glue if that form of gelatine be employed, as some of the coarser kinds are not to be trusted for mounting valuable photographs. We should recommend one or other of the many forms of gelatine now purchasable under the name of "gelatine" glue, being, as our readers are aware, simply another name for a coarser sort of that substance.

It is important to note one point in regard to mounting with solutions containing a large proportion of spirit, and that is, the print before being coated with the material must not be damped. If this be done the whole meaning of the process is lost sight of, and expansion of the print will follow as usual.

Many photographers, however, do not care to make use of this alcoholised glue on account of heat being required to melt it, which entails so much loss of time when a few prints only are required. Beyond that, also, there is a feeling that glue mounting requires defter manipulation; and, as dexterous mounting is a qualification which takes some time to acquire, preference is often given to other substances. A solution of "gum arabic" is often used, and it forms a very handy mounting material. Further: if for any purpose the prints need removal at some future time it is readily done when the acacia gum is used. It possesses, however, one grave disadvantage, and that is its liability to turn acid with keeping. This should lead, if not to its entire rejection, at anyrate to its most careful use; for, whatever opinions may be held as to the cause of fading, no one would suggest the safety of placing a print in constant presence of an acid substance. We may point out that when this substance is used the liability to become acid will be greatly lessened by dissolving the gum without the aid of heat. Much more time is needed to bring about the solution, but when finished the preparation is entirely different from that made when heat is employed.

Of all favourite mountants, however, we believe starch takes the lead. It is cheap, easily made, and readily used; though it will not keep long after mixing, a very small quantity only is required. Starch paste should not be used after it has once begun to change and lose its gelatinous character. Any of the forms of starch will answer, but we strongly recommend those made from maize, and sold under the name of "corn flour," &c. Being manufactured for dietetic purposes the absence of chemicals may be assumed, and the purest form of starch thus ensured. Prints mounted with some of these starches are most difficult to remove; in fact, it is almost impossible to stir them when once they are dried and rolled.

Dextrine, though made from starch, can scarcely be termed a form of starch, as its chemical character is altered. It has, however, been little recommended for mounting, perhaps on account of suspicion of chemical contamination when made by other processes than the torrefaction of starch. It should, notwithstanding, be valuable, as it is soluble in dilute alcohol. We believe, however, that there is still much to be learnt about mounting materials. A mixture that would be adhesive without trouble, require no heating before being ready for use, keep good for a long time, neither cockle the mount nor distort the print, and, finally, would be ready for use at a moment's notice, would be of great service and find a ready sale.

Such a mountant would, in all probability, require to be composed of more than one ingredient, and difficulty is here at once to be perceived. The properties of the mixture of some of these materials are not the mean of their individual qualities. For example: mixtures of some gums and starch will remain fluid on account of their viscosities being of different natures.

The following facts, however, which are embraced in the article to which we have alluded, contain the germs of much knowledge that is needed to form such a mounting material as we describe, and may well be studied by those who would experiment in that direction:—Tragacanth gum dissolved in water in the proportion of 196 grains per pint will have as much body as two and three-quarter ounces of starch or four and a-quarter ounces of dextrine. It is difficult to dissolve; but the best method is to make a stiff paste first and gradually let it down with water.

Starch paste can be mixed with tragacanth. This mixture is stiffer than either used separately. It keeps for a long time without change, and the paste is more yielding and easily spread than either substance by itself.

Gum acacia alone requires a large quantity to be mixed with water to get much body. Half-a-pound to a pint gives a free-flowing liquid scarcely thick enough for pasting photographs. The danger of using it too thin is that it is apt to penetrate the paper and render it translucent, just as a spirit paste would act.

These few data comprise, with the large amount of knowledge which is already on record about gelatine, a nucleus of facts on which we trust yet to see raised a new mountant for universal use possessing the characteristics we have described.

From an announcement in our advertising columns it will be seen that the programme of the next exhibition of the Royal Cornwall Polytechnic Society is now published. Information on the photographic department may be obtained, as usual, from Mr. William Brooks, of Reigate.—The programme of the forthcoming exhibition of the Photographic Society of Ireland is also announced elsewhere.

According to a paragraph in *La Nature*, the purity of india-rubber—an all-important point as regards its suitability for dissolving in benzole, &c., for mounting and other purposes—may be ascertained by placing it in a jar of water. If pure it will float, but if adulterated with foreign matter it will sink. Pure rubber also resists the action of all liquid acids.

A correspondent of the same journal sends an account of a curious experiment he has made, and fills a whole column in describing how he has succeeded in obtaining a phosphorescent photograph. His method is simply to place a glass coated with several layers of phosphorescent paint in the camera, and to expose in the usual manner! He further explains how the force of the image is influenced by the aperture of the lens and the brightness of the landscape, which conditions, when favourable, allow him to obtain his views in some minutes. If it failed in brightness a cure was to be found by breathing upon it. By holding it over a slightly-hot smoothing-iron the image became very brilliant. Really, we thought that the time had gone by for this sort of thing. We can imagine the disgust of an experimenter after exposing a plate (say) early in the morning at the appearance—or the want of it—of his image when he came to examine it at night. If a phosphorescent image of the kind does possess any value it would be far better to expose under a transparency, but Mr. Woodbury's method would be still better. Phosphorescent photographs, however, have never "taken."

Some of our readers may remember the excitement caused some time—perhaps twenty years—ago by the announcement that an acarus had been discovered capable of existing in and, indeed, thriving upon nitrate of silver. It has been asserted that poison is a mere question of quantity, and, as we know, nitrate of silver in small doses is sometimes administered as a medicine; but we question whether patients themselves, if permitted a voice in the matter, would not almost prefer to take their chance of a fatal termination without its use if they knew the repulsive-looking objects they would surely become after a course of silver nitrate—their faces irremediably stained of an ashen, deadly grey colour.

No one, however, to our knowledge ever suggested a strong bath of cyanide of potassium as a likely medium of existence for any organised body. But that even this deadly poison seems looked upon as a natural delicacy by one form of animal life has been found by Sir Frederick Abell, who, in speaking of barnacles off a ship's bottom, states that he placed "some of these gentry in a strong solution of cyanide of potassium, but he found it had not the slightest effect upon them!" The members of this family, however, surely succumb to the virtues of pure water, a short immersion in fresh water killing them off. Rather a hard nut for Sir Wilfred Lawson!

MM. Depière and Clouet have lately been experimenting upon the bleaching action of sunlight and the electric light. They find both lights to bleach, but that, though the action is not confined to certain rays, it is unequal. Strange to say, they find the yellow rays the least active and the red the most.

Our readers may remember that a number of scientific men are engaged in endeavouring to determine the practical units of light and electricity. Their final meeting took place on Monday last. Sir W. Thompson, Messrs. Preece, Hughes, Adams, Jenkin, Foster, Graves, Hopkinson, and Captain Abney represented England. If a unit of light of a really practical nature and not too intricate in the mode of its production be devised there will be no body of men to whom it will be of more use than to photographers. The "ten, twenty, thirty, &c., times wet plate," though to those familiar with collodion working possessing a really practical meaning, has become a mere formula — meaningless, misleading, and utterly untrustworthy—with regard to many of the plates put upon the market.

We thought that every one knew the history of the discovery of bromine by Balard, who pointed out its elementary character, being thus more acute than a well-known chemist who had isolated it previously, but failed to discern its elementary nature. Believing it to be a compound of iodine he laid it aside. This, no doubt, is the "story" referred to by Professor Thorpe in his late most interesting lecture on Wöhler, where he says—"We all know the story of the young chemist whose unscientific use of the imagination cost him the discovery of the element bromine." This sentence is referred to by a writer in the *Chemical News*, who asks for its elucidation, its explanation being simply the facts above narrated.

LIME-LIGHT EXPLOSIONS AND THEIR PREVENTION.

As I was not present at the reading of my paper, entitled *Notes on the Lime Light*, at the last meeting of the Edinburgh Photographic Society I should be obliged by your inserting the following remarks on the discussion which followed it.

In reply to Mr. J. M. Turnbull, I may say that the ether tank which I use is not covered with any coating of a non-conducting material, and I think it would be an objection if it were so. The copper sides of the vessel become very cold by the evaporation of the ether, and the heat of the lecture-room helps to restore them to a proper warmth. I am more afraid of depression of temperature than of heat in this process.

I place the ether tank on the table as near to the lantern as possible, so that I may be able to use a short connecting tube. If the tank were on the floor a longer tube would be needed, and the chance of accident by a rent would be increased, the ether vapour being absorbed by the india-rubber, and tending to make it rotten. Although the tank is above the bag no ether can syphon back into it, a reserve chamber being provided for the express purpose of preventing such a calamity; and in the latest edition of these tanks, which I think is the best, the gas does not go through the ether at all, but simply passes over its surface by a long and tortuous channel. Such being the case, it is comparatively immaterial which tap you open first, provided you open them both at the same time. But you must not open the oxygen tap and leave it with the hydrogen tap closed, or some diffusion of ether vapour backwards might gradually take place in spite of the pressure from the bag.

Mr. Turnbull does not say why it is that he has so little faith in back-pressure valves, but, if it is because they take off too much of the forward pressure of the gas, I advise him to place them for the future *upon the nozzles of the bags*, and he will find them to work better in every way than when they are attached to the jets.

Mr. G. A. Wilson states that his objection to the pumice for safety tubes is that it is apt to become pulverised and to be blown into the nozzle of the burner. I have had to complain of the same defect, and unless it can be remedied it will be fatal to its use. A friend suggests to me that *very coarse* emery powder—which, he says, is sold in commerce—might, perhaps, do as well.

Mr. Wilson's idea of a safety chamber, consisting of a common piece of cane inserted in the tubing, pleases me very much. I cut a piece an inch long and tried its effect on the pressure of the gas; the diminution amounted to about thirty per cent. In the ethoxo process a safety tube on the H nozzle of the tank would be of great service even if it were not *absolutely* perfect. In two out of three accidents of which I have heard the ethoxo gas was not actually explosive, but burnt with great fury, exactly as Mr. Wilson describes; and I can quite well imagine that under such circumstances it would stop at the cane, and give the lecturer time to turn the H tap of the tank and put it out. I hope some day to try this simple tube side by side with the pumice safety chamber, and if I obtain satisfactory results I will report accordingly.

Mr. G. R. Baker's paper on *The Lime Light.*—This paper, written by one who has a practical knowledge of his subject, will be found to contain some valuable hints. Like Mr. Baker, I have come to the conclusion that an elongated, incandescent area of lime light is better than a "spot." Mr. Lewis Wright, working with the microscope, would not perhaps agree with this, because the requirements are different. The light radiating from an incandescent area is not brought to a true focus by the condenser, and hence much of it is lost in passing through the objective of a microscope. It will pass easily, however, through a portrait objective, and a bundle of rays large enough to nearly cover the glass will be seen issuing from the front lens. For the microscope an incandescent "point" is what you have to aim at. To secure this as nearly as possible the lime light must be brought almost close up to the burner, and a strong pressure put on the bags to produce a very intense heat. The flame will then drill a circular hole on the cylinder of lime, and you must be careful to rotate it frequently, or the flame will strike off at an angle and break the condenser. Keep the oxygen tap rather fully on, so as to prevent the little cone of imperfect combustion in the centre of the flame from touching the lime and causing a black nucleus. As regards the angle of incidence of the burning gases, it should be as near a right angle as you can get without throwing a shadow on the screen.

To produce the "elongated incandescent area" you make the nozzle of the jet *straighter*, as Mr. Baker observes, about twenty-five to thirty degrees of incidence, or, as I prefer, *you remove the nozzle, bent at 45° as directed for the microscope, to a distance of a quarter of an inch from the lime;* the spot will then be less intensely heated, but it will be larger, and, according to my experience, will give quite as good a light upon the screen. The advantages will be manifold, for a rotation of the lime once in ten minutes or a-quarter of an hour will be sufficient, and the point of the burner will neither choke up nor burn away.

The O tap should not be turned on quite so fully when the jet is a-quarter of an inch from the lime, because some oxidation takes place in passing through the surrounding air. Keep the cone of imperfect combustion about an eighth of an inch long.

Mr. Baker asks what percentage of pressure is lost by passing through one of Broughton's pumice safety chambers. I should say about twenty-five per cent., so that the one hundredweight on the bag is reduced to three-quarters of a hundredweight. I have not tried these tubes with the most explosive form of oxygen and hydrogen, but it would be quite necessary to do so before making any report. The plan I follow is to take a biunial lantern, burning the ethoxo gas, and to turn on the O tap until the small interior cone of imperfect combustion in the centre of the blowpipe flame *almost* disappears. The ether vapour and oxygen are then present in the right proportions to form the most violently-explosive mixture, and you can fill any number of balloons by means of the dissolver, leaving the taps untouched.

Gas Dissolvers.—Mr. Baker's remarks under this head are useful. I have known one of the two lanterns to go quite out in dissolving, the explanation being that the screw which secured the plug had become loose in working, and the plug had shifted in consequence. If the plug were to shift it is obvious that the gases might pass round it to some extent, and this would be a source of danger.

T. Frederick Hardwich.

THE MIXING OF EMULSIONS OF DIFFERENT SENSITIVENESS.

The question of the effect produced by mixing emulsions of different sensitiveness came up at a recent meeting of the London and Provincial Photographic Association, and there was a short discussion on the subject.

The question asked was, so far as I recollect, something to this effect:—"Will the result of mixing an emulsion giving 10 on the sensitometer with another giving 20 be an emulsion giving 15 or not?"

The question is lacking in definiteness, as there is no mention of the quantities to be mixed. It is, however, to be assumed that equal quantities are intended, and probably equal quantities of silver bromide rather than equal quantities of actual emulsion. The experience I have had in mixing emulsions tends to show that the effect of mixing two emulsions containing equal quantities of silver bromide is not to get a sensitiveness which is a mean between the two, but to get somewhat greater sensitiveness.

Judging merely from hypothetical reasoning before trying the experiment, I came to the conclusion that the addition of a slow to a rapid emulsion should not decrease sensitiveness at all. I judged that, because in the mixture there were present the particles of silver bromide which went to form the more sensitive emulsion of the two, the sensitiveness should be nowise reduced, but that a thinner image would be produced, the particles of the slower emulsion not being reduced at all except in the higher lights, and these only to a moderate extent.

This I found to be a mistake, and experiments made by mixing emulsions of not very great differences of sensitiveness—say not more than four to one—brought me to the following conclusions:—

First: the particles of the more sensitive emulsion of the two require a greater amount of light to produce a developable reduction than before mixture.

Second: particles of the slower emulsion, which, with the emulsion used alone, would not be reduced at all, are reduced in the presence of the more rapid emulsion.

Thus it appears that by the mixing of equal parts of two emulsions whose sensitiveness does not differ greatly we get an emulsion more rapid than the mean of the two, and giving about as great density of the high lights and also of the details as would be got with the more rapid emulsion alone. I should say that by "mean" here is meant geometric mean, not arithmetic. The sensitiveness indicated by the arithmetic mean on the sensitometer is a geometrical mean sensitiveness. For example: supposing plates giving the figures 10, 15, and 20. Here the middle figure is the arithmetical mean of the first and third figures. The sensitiveness of the plates will, however, bear as nearly as possible the ratios of the figures 1, 4, and 16—the middle figure being here the geometrical mean of the other two. An arithmetical mean would be $8\frac{1}{2}$, and would in the case supposed be as nearly as possible represented by 18 on the sensitometer. I am inclined to think that by the mixing of equal quantities of emulsion of different sensitiveness a sensitiveness much more nearly the arithmetical than the geometrical mean is gained.

When I say that where two emulsions of different sensitiveness are mixed silver bromide of the slower emulsion is reduced which would not be reduced were the more rapid emulsion not present, it

THE LATE REV. F. F. STATHAM, M.A. F.G.S.
[For 25 years President of the South London Photographic Society.]

INK-PHOTO SPRAGUE & Co LONDON.

must be borne in mind that I have imagined the sensitiveness of the two not to vary enormously. Mr. A. Cowan gave, at the meeting mentioned, an account of an experiment made by him, in which two emulsions differing enormously in sensitiveness were mixed, with the result that an emulsion somewhat slower than the more rapid was produced, whilst a very thin image resulted, thus apparently showing that the bromide of silver of the slower emulsion had not been reduced at all, and had simply acted as so much inert matter.

To proceed from general statements to practical details: I may give a few instances in which I consider that two emulsions may be mixed with advantage.

The principal of these is where an emulsion of great sensitiveness is made by the ammonia process. All who have experimented in this direction must have discovered that an emulsion which has been made very sensitive by the use of ammonia is very transparent, requiring a very thick coating to be applied before a film through which it is not possible to see the shape of a gas flame is obtained. It is possible, however, to add to such an emulsion enough of a boiled emulsion to give considerable opacity without reducing the sensitiveness perceptibly, whilst at the same time the quality of image is improved in every way, the density being increased instead of the reverse. I think the best way of explaining the matter will be to give the actual quantities which I have used as an experiment.

An emulsion is made by the ammonia process, four hundred grains of silver nitrate going to make up from twenty to twenty-two ounces of finished material. I suppose a sensitiveness represented by 22 to 23 of the sensitometer to be reached. The emulsion will be very transparent; at anyrate, an ammonia-made emulsion of the sensitiveness named is always very thin in my hands.

A boiled emulsion is made as follows:—

A

Silver nitrate	100 grains.
Water	1 ounce.

B

Bromide of potassium	80 grains.
Gelatine (Nelson's No. 1)	15 „
Water	1 ounce

The solutions are heated and emulsified in the usual manner, and boiling is performed as long as would be considered desirable to produce a fairly-rapid plate. In my own practice I should boil till the emulsion had changed from red by transmitted light to blue, and should continue the boiling for a similar time to that which was necessary to bring about the change.

After this the emulsion is allowed to cool. When cold there is added to it fifty grains of gelatine in the dry state. This is allowed to soften. Heat is applied to mix the gelatine and sensitive silver bromide. The emulsion may now be at once added to the ammonia-made emulsion; or if the latter has been washed the boiled emulsion may be allowed to set, be washed separately, and be then added. In any case it will be seen that there is only one quarter of the less sensitive silver bromide than there is of the more sensitive. It has been added without increasing the bulk of the emulsion by nearly one quarter, whilst it will be found that the covering power has been quite doubled. The sensitiveness will not be decreased, whilst even with films half as thick denser images may be got from the mixed emulsion than from the ammonia emulsion alone.

There is another procedure occasionally adopted in the manufacture of emulsions, which practically amounts to the mixing of a slow, opaque emulsion with a rapid, transparent one. This consists in adding to an emulsion as nearly as possible before it sets for washing nearly enough silver nitrate to convert the excess of silver bromide.

I shall again give a definite example. Suppose that in the case of the first of the two emulsions which I presumed to be mixed there was used with the 400 grains of silver nitrate 320 grains of potassium bromide: this gives an excess of forty grains of potassium bromide, requiring fifty-seven grains of silver nitrate to neutralise it. Now, suppose the process of digestion with ammonia to be complete and the bulk of the gelatine to be added. We may add (say) forty grains of silver nitrate to the emulsion. On account of the presence of the large quantity of gelatine this will form, with the greater part of the excess of bromide of potassium, an exceedingly-fine emulsion, which will be very opaque.

The result of the foregoing procedure is to increase considerably the opacity of an emulsion; but whether or not the silver bromide last produced is ever actually reduced to form part of the image I cannot tell. Seeing that the last produced silver bromide must be very much less sensitive than the first produced, I doubt it. It is possible that so much inert matter might have the same effect as the silver bromide produced at the end of the process; but whether this be the case or not an increase of density of film is gained which enables the emulsion to go considerably farther than it otherwise would. The sensitiveness of the emulsion is not perceptibly decreased, whilst silver bromide, used merely to produce opacity of the plate, has this advantage—that it is dissolved away by the fixing bath.

A very good reason for the mixing of two or more emulsions is that by so doing uniformity of result is gained. It is very difficult, in working on a small scale, to make emulsions in succession which shall be each of the same sensitiveness as the one before it. It is not, however, very difficult to so work that the mean sensitiveness of any one set of three or four emulsions shall be very nearly the same as the mean sensitiveness of any others. And although the mixing of each of these two sets of three or four sets of emulsions may not give a sensitiveness which is the mean sensitiveness of the three or four, it will give the same sensitiveness in each set as in another.

Mr. A. Cowan has often recommended the mixing of several emulsions for the sake of gaining uniformity; and the practice is, I believe, adopted by many commercial dry-plate makers.

W. K. Burton.

THE LATE REV. F. F. STATHAM.

The funeral of the late Rev. F. F. Statham, whose portrait we give this week, took place on Saturday last, as announced in our last issue. The body was borne from the Rectory to St. Peter's Church (of which, not St. Mary's, as was stated last week, he was rector), where the first portion of the funeral service was performed.

The church itself was crowded in every part, and an immense assemblage thronged the approaches. After the preliminary service the funeral procession, comprising the hearse and half-a-dozen mourning coaches, accompanied by 400 of the West Surrey Rifle Volunteers and a detachment of the P Division of Police (of both of which deceased had been chaplain) proceeded to Norwood Cemetery. The line of route was thronged with sympathising parishioners and others who had known Mr. Statham. Owing to the roads in a portion of the intended line of route being under repair it was necessary to make a considerable *détour* which delayed the arrival at the cemetery by nearly two hours. On reaching there a large crowd, of probably fifteen hundred or two thousand persons, was encountered, many having been waiting for some hours. The three bands of the 4th Surrey drew up at the entrance to the cemetery, and, as the *cortége* passed in, played the "Dead March." The coffin—which was draped with the Union Jack and literally covered with wreaths and flowers, amongst which were offerings from the South London Photographic Society and the Photographic Club—was borne in a handsome open hearse, presenting a singular contrast to the usual sable surroundings of the funeral ceremony. This, accompanied by a guard of honour of the 4th W.S.R.V., was followed by the line of mourning carriages and the remainder of the volunteers, who paraded with side arms only, with the exception of the firing party.

As the procession wended its way, attended by the great crowd of mourners, across the picturesque cemetery the rain, which had been threatening for some time, commenced to fall and the aspect of things became dismal in the extreme. The contrast between the white marble of the memorial erections and the outline of the Crystal Palace, at no great distance—scarcely picked out from the dull, leaden sky—was especially noticeable, the whole surroundings being mournfully *apropos* to the occasion. The service at the grave was brief, being conducted—as was that at the church—by the Rev. S. P. H. Statham, military chaplain at Aldershot, and the Rev. Sherrard Statham, of Birmingham, sons of the deceased. The coffin, of plain oak, was lowered into the grave with deceased's bible and parade cap; and after the close of the ecclesiastical part of the service three volleys were fired over the grave by the members of the 4th Surrey.

Amongst the throng of mourners the following connected with photography were present: — Messrs. F. A. Bridge, F. York, E. Cocking, T. Sebastian Davis, John Stuart (Glasgow), J. Traill Taylor, E. W. Foxlee, A. Cowan, J. A. Harrison, W. B. Bolton, J. J. Ayling, W. Cobb, A. L. Henderson, J. Garrett, C. Darker, and F. W. Evans.

As an extended notice of the deceased gentleman's life we cannot do better than give the following abstract from the *South*

London Press, a local paper edited by an intimate friend of Mr. Statham during many years.

The Rev. Francis Freeman Statham, who died at St. Peter's Rectory, Walworth, was the third son of Edwyn Statham, of South Lambeth, and formerly of Nottingham, and was born in London on the 8th of September, in the year 1814. He was educated in various schools, but at the unusually early age of eighteen he purchased the goodwill of the Newington Grammar School, then a large and prosperous academy. During the time that Mr. Statham acted as principal the school still further increased in size and popularity, and there are many "old boys" who remember the instructor of their youth with affection and esteem. The whole object of his life, however, was not centered in training and teaching the young; for, with that earnest assiduity which has always characterised his whole career, Mr. Statham applied himself to the study of science, and at the same time by constant mental toil perfected his knowledge in divinity and mathematics so as to graduate at the University of Oxford.

At the age of nineteen Mr. Statham appeared before the public in the *rôle* of a scientific lecturer, sowing the seeds of that unvarying popularity which has always attended him in that character. His "two very interesting lectures on *Hydrostatics and Hydraulics*" were attended with so much success that in the same year (1834) he was invited to appear before an audience in the Royal Institution, Clifton, the London Mechanics' Institute, the Southwark Literary Institute, and was also engaged to give a course of six lectures on electricity at the Bristol Mechanics' Institute. It was during the fulfilment of this engagement that he became acquainted with a Miss Kington, to whom he was married in Clifton Church on June 16, 1836, and who, still living, mourns her irreparable loss; for not least amongst his many virtues must be counted his untiring affection as a husband and his unselfish devotion as a father.

Mr. Statham was ordained deacon in 1843, by the Bishop of Winchester, and, in the following year, priest by the Archbishop of Canterbury, and was appointed to the chaplaincy of the workhouse and then to the curacy of St. Peter's, Walworth. The chaplaincy of the union he retained for over thirty years, and his curacy was created an incumbent's living in the year 1848. Of the immense activity which Mr. Statham displayed in past years in the parish those who have only seen him in his later years enfeebled by much toil, mental and bodily, can never imagine. In the great cholera year (1848) Mr. Statham buried four hundred and seventy-seven parishioners who fell victims to that scourge. Walworth in those days was a village, in a comparatively open country, intersected with hideous open ditches and sewers. These by his constant agitation were covered or filled in. Schools were collected for and built, visiting societies were formed and presided over, and all the numerous duties of a parish clergyman were regularly and spiritedly performed.

That Mr. Statham's death is a calamity which will be felt beyond the radius of his parish cannot be doubted. His influence extended to many distant parts of the kingdom, for his readiness to give assistance by preaching, lecturing, or in anything in his way, was so great that there is no diocese in England in which he has not officiated or lectured. Indeed, his willingness to give voluntary and gratuitous services helped considerably to augment the mental friction and exhaustion which at last overpowered the body. For twenty-five years he was honorary chaplain to the P Division of Police, taking a service regularly every week and visiting whenever needed. He was President of the South London Photographic Society from its foundation. The chaplaincy to the 4th Volunteer Battalion Royal West Surrey Regiment has been held by him for nearly the same period; whilst the lectures he has delivered in aid of various charitable objects are simply innumerable. From this point of view alone his excessive willingness to oblige and benefit others even at his own loss renders him a remarkable man. But for many other reasons we may truthfully assert that South London possessed no greater resident. The grasp of his mind was immense—his genius indisputable. There are not many men who, besides possessing a competent knowledge of the classics, are also good mathematical scholars; but there are very few indeed who, in addition to these, can speak two or three modern languages, lecture and write upon many branches of science, history, political economy, histories and customs of many nations, ancient and modern; who can write well-reasoned and original theological essays with as much facility as they can write a leader in the paper, a prologue for a play, a libretto for a comic opera, a skit upon some public topic, an article upon photography, papers on geology and on mechanics; or compose a chant or a hymn with equal skill as they can fill in the proper scores for a brass band, or compose the music for operettas. Yet Mr. Statham did all these things, and did them well. His book, *The Message of the Spirit to the Seven Churches*, and nearly forty other published sermons, testify to his ability as a divine, while it is not difficult to find copious proof of his capability to write upon all the fore-mentioned subjects in various newspapers and other publications. Before the Geological Society, of which he was a member, he read several papers, published in *The Geologist*, as he did before the British Society upon *Applied Mechanics*. Under the name of "Sydney Vernon" he has published several musical compositions of no mean merit, and there is more than one of his operettas still produced on the platforms of various institutes who patronise entertainments after the style originated by German Reed, whilst many newspapers, comic and otherwise, contain numerous proofs of his skill in writing humorous poems and skits. Indeed, the number is so large that if it be possible to collect them they will be made into a volume and published; added to which the variety of subjects upon which he lectured was simply marvellous—in fact, any subject suggested to him as suitable—and, as we have already said, applause and approval were never wanting. His success in lecturing consisted mainly in his complete power over language and to the rich vein of humour which he possessed.

The funeral sermon was preached on Sunday evening last, the 27th ult., by the Rev. D. Moullier, rector of Holy Trinity, Newington.

Our picture is from a photograph by Mr. William Cobb, of Woolwich, and is, we believe, the latest portrait taken of the late Mr. Statham. To Mr. Cobb, and also to Messrs. Sprague and Co., we are indebted for the trouble they have taken to enable us, at very short notice, to give the portrait of our deceased friend.

THE ETHOXO-LIGHT.

In the report of the transactions of the Edinburgh Photographic Society, in your issue of the 18th ult., Mr. G. A. Wilson says that the pumice chamber, after being used or knocked about, is liable to deterioration through pulverisation of the pumice. I do not understand how this can be, unless Mr. Wilson plays shuttle-cock with it; for I have never yet had my nozzles stopped up from that cause, and I believe I have used them oftener than any other person. I, too, have used cane for the same purpose, but found it to require too much pressure to work it at its best; and if Mr. Wilson had hesitated many more minutes in his experiments with it (narrated by him at the meeting) he would have come to the same conclusion that I have—that it is not advisable to interpose any organic medium to intercept flame. I do not as yet consider my pumice chamber *perfect*, but I hope shortly to have one constructed combining the best points of the suck-back and flame-chamber combined.

With reference to the remark anent the safety of the ethoxo for dissolving: I may say that I have used it every season for five years. I have on but very few occasions used a single lantern, and I have never yet had any trouble in dissolving with it.

Another mistake Mr. Wilson has fallen into is that ordinary gas will explode. Oxygen gas, although a supporter of combustion, will neither fire nor explode; nor can hydrogen be made to do the same, unless mixed with air or oxygen.

Mr. W. M. Turnbull seems to place reliance upon the generator being jacketed. This is really a defect rather than an advantage, as it prevents the ether getting the benefit of what heat there is in the room; for during the evaporation of the ether there is a very great diminution of temperature in the generator, and this is in no way obviated by any external covering. With regard to the construction of a generator, that the ether cannot be blown back: this is what I have already done by the construction of reserve chambers, which, if the proper quantity of ether be put in, will not blow back, even if the generator be placed on its side, or upset accidentally.

Pressure is one of the best safeguards against explosions, and of this I am always careful to have plenty; also to protect all tubes and bag with forms or other available protection against stoppage by the accidental pressure of the foot. Mr. Lewis Wright's suggestion to turn on the H tap first I fully endorse, as I have by experiment found a pressure in the generator, equal to four inches water-pressure, at a temperature of sixty degrees.

W. Broughton.

THE "HAPPY MEDIUM;" OR, DARK-ROOM ILLUMINATION.

IN THREE CHAPTERS.—CHAPTER I.

Although the fervour of the discussions upon the above important subject seems to a certain extent to have cooled down during the last week or two, I feel that the matter possesses sufficient interest to the readers of this Journal to warrant the approach to it by anyone who has carefully and honestly studied the question in its various aspects, as I claim to have done. I have not only debated the question in my own mind from various points of view, but I have made a few experiments. I have given a demonstration to a practical club of photographers. I have carefully perused all the writings of the past year that I can find. I have compared notes personally with several eminently-practical men; and I have consulted medical men as to the effects of various coloured lights upon the human eye. As a matter of fact I have, in a loose way, collected so much information on the subject that my great difficulty is going to be in the promulgation in a connected and concise form of the information I have gathered from so many sources. I know that my remarks must appear to men of better-ordered minds than myself sadly disjointed; but from such I claim indulgence, and to such I submit that I shall advance in good faith, and without prejudice to any man or to any theory, my ideas and convictions on the subject which I treat here.

It is a curious fact, but it *is* a fact, that mankind insists on running into extremes; that the "happy medium"—in this case the "light medium"—is the very last mark that we ever hit. The present or late discussion on dark-room illumination is a fine example of this idiosyncracy of humanity. We have the premiss that all light is hurtful to the sensitive salt of silver over and above what passes through the lens from the object being photographed; so we have a set of men who say—"Let us work in total darkness." We have another axiom—that in order to see what we are doing we must have a certain amount of light in our developing-room. Up starts a set of men who exclaim—"Let us work in broad daylight, or as near as we can get to broad daylight, without instant and utter ruin to our plates!" But this is not all. We find some men saying—"Red light, *used as I have been using it*, hurts my eyes." These men banish red light entirely from their consideration and laboratory. Orange light offends and hurts another using it in a certain quantity and through a particular medium. He, too, abolishes orange light in every quantity and shape. But the greatest human perversity takes this form:—"Red light (or orange light) hurts and offends me; therefore it hurts and offends my neighbour. Consequently, I shall inveigh against red (or orange) light, and despise and execrate the man who pretends to prefer orange (or red) light!" I write this in all earnestness, and not merely trying to make a clever satirical epigram. I might concisely sum up the whole gist of all that has been written and spoken on the light question in a few words such as—"Use any light you like, in any manner and quantity you like, so long as you get efficiency without damage." But in order to guide tyros and others in their choice of a light much has been written, this article is being written, and probably much more will be written.

If we rightly understand our chemicals and our light, all light affects the sensitive salts used in photography; but if we are rightly to conduct our operations we must have *some* light. Certain constituents of light affect our sensitive salts less than others, so that our course is thus far indicated. We must use the least hurtful parts of light for our operations, and even of these parts we must use as little as possible consistent with power to conduct our operations. These propositions appear to me to contain the kernel of our nut. Some of the propositions can be settled scientifically and accurately; some cannot, being matters of taste dependent on our requirements, our visual powers, and our idea of the "happy medium." Given a certain "sensitive salt," science can determine what constituents of light affect the salt least and what most; but introduce a mixture of sensitive salts, a combination of light-constituents, a diversity of human eyes, and at once science, or accurate computation, is lost, and "give and take" is the order of things. Now, I have built up a fine wall which I cannot break down, but if I can manage to displace a few stones I may make a little breach through which my reader may perchance wriggle his body, and so reach the treasure within—the "happy medium."

If no light at all were required for the development of a plate this article and all others on the same subject would be superfluous; but light of some kind is required. For the preparation of gelatine plates light is not required; blind people and machinery can do the whole affair, so that I put these operations out of consideration. By no means that I know of could a blind person judge of the progress of development on a sensitive, exposed plate. But various intensities of light are required for various purposes and by various operators. One man's eyes are better than another man's; one man's eyes are better in a particular colour of light than his eyes in another colour. Already we have got an element of uncertainty. Again: where exposures have been one after another made upon similar objects in a slightly-varying quality of light, as in studio work, less careful examination of the developing plate is required than where exposures have been made on landscapes in different situations on very different objects, and during a period extending over days or even weeks. Another element of doubt—another instance of the necessity for the "happy medium."

My own work consists entirely of landscape work; my exposures are made over periods of weeks or even months, and these plates have to be developed all at one time. Therefore I shall gain credence when I say that I lean towards abundance of light for my developing-room. But I also lean towards very sensitive plates. I abhor a negative anything like fogged; so I shall again be believed when I say I use as "safe" a light as I can get. My object, then, must evidently be to find a quality of light that I can use in large quantity without danger to the purity of my negatives. And here I proceed to detail some experiments I have made, partly for my own instruction in private, but particularly in presence of a club of practical men in Edinburgh.

The weak part of all such experiments is that, though they are conclusive enough under stated conditions, they cover no other circumstances than those under which they were specially conducted; and whatever may be the result of experiments conducted by one man, trying to elucidate one question, with one material, at one time, under one set of circumstances, a totally different result might arise were all or any of these conditions altered. However, I give what really occurred in the course of my experiments with three media:—1. Glass, ruby flashed on one side only. 2. The same glass with a thin coat of matt varnish next to the light. 3. One thickness of "canary medium," as presented to the Club by Mr. A. L. Henderson, of London. The Club consists of thoroughly practical men; and when I say that there were present, among other well-known names in our ranks, Mr. J. M. Turnbull, Mr. Tunny (a photographic patriarch), Mr. Hume (chemist, microscopist, and photographer), Mr. Jamieson, Mr. Wm. Forgan, &c., it will be understood that what we did was accurately and carefully done. The lamp used was large, the sides about $12 \times 7\frac{1}{2}$ inches, the burner a good large fishtail gas burner, and the sides "glazed" with the materials named above. The plates used were Wratten's "drop-shutter" quarter-plates—a newly-opened box; the tests, tablets of Warnerke's sensitometer; and the development conducted in one dish with one dose of alkaline sulpho-pyrogallol. My idea was to test the illumination and proportionate safety of the media, and I began by handing the Chairman a railway time-table, covering consecutively two sides at a time of our lamp, and trying at what distance he could read the small print in the time-table by the light of the uncovered side of the lantern. With the clear ruby glass he could read at seven feet distance from the lamp, with ruby glass and matt varnish at four feet, and with "canary medium" at three feet. So much for illuminating powers.

We then took three of the Wratten plates, three sensitometer tablets, and three printing-frames, and exposed them (simultaneously) for precisely two minutes to the three sides of the lantern. To the ruby side we exposed No. 1 at seven inches distance, No. 2 to the ruby and ground glass at four inches, and No. 3 to the canary side at three inches. Developing all together as described above, the ruby-glass-exposed plate gave about 11 on the sensitometer, the ruby-and-matt-varnish plate about 6, and the canary 4 or 5. I speak approximately as to sensitometer numbers, because there appears some doubt as to what number ought really to be quoted in the use of such an instrument. In this experiment the canary medium had certainly the best of it, and I confess now, as I confessed then, that I was vastly surprised at the result; the "reason why" I shall shortly tell. It will be understood that I had and have no prejudice in favour of any particular medium, and all my endeavour was to make a fair comparison between the materials employed.

The fact, then, which I consider so far proved by my experiment—that this pale yellow-greenish light had the least effect upon my sensitive plate—set me thinking very seriously. In common with a great portion of photographers I had always understood that anything approaching to a pale lemon colour was a very delusive substitute for light-filters of orange or red tints, and I had also believed that a spectroscopic test of any material used for a dark-room lamp or window was a conclusive test; and here I found a material that, examined spectroscopically, utterly failed to pass as a safe medium, acting with greater safety in proportion to its illuminating powers than even a ruby glass which stood the spectrum test very much better, and also the same ruby glass with a light-diffusing material added. Considering what I had always been taught to believe concerning the action of light on sensitive salts, it is little wonder I was astonished.

I have repeated my spectroscopic examination of a number of substances and colours used for lamps and windows in the dark-room, and all my observations tend to prove that there is some great error in the theories usually laid down as to the action of the various parts of light on our plates. Today (24th April), with a student's spectroscope, by Browning, I have examined flashed and stained ruby glasses and orange papers oiled and plain, also canary medium and Mr. Debenham's combination, and certainly the spectroscopic tests have not at all been borne out by actual experiment with gelatino-bromide plates. I have only one inference to draw, namely, either the spectroscope is a false instrument, or our accepted theories as to the action of light on bromide, chloride, and iodide of silver are, if not false, at least seriously deficient in some respect. I need not say that I accept the latter alternative. The canary medium under spectroscopic examination passes all the green rays and some of the blue. Mr. Debenham's green glass and yellow paper do about the same, but cut off some of the red. The green glass alone has the latter effect. A double-flashed ruby glass allows very little except red to pass; so, too, does a stained red glass. Orange in any shape passes a considerable amount of green; and yet on trial—very careful trial—I found plates as little fogged by canary and Debenham as by any of the other media, or almost as little.

Doubtless my readers will say that for all these reasons I use canary medium or Mr. Debenham's combination for my dark-room window. Such is not the case. I tried the canary some time ago, and the green glass and yellow paper quite lately; and after going to considerable trouble and expense I undid all I had done, and replaced my ruby glass just as it was before my mind was unsettled by the late discussions. And why? Because I could not see with the yellow-green light, and because all yellow-greens are obnoxious to me. And there lies the reason why I deprecate all attempts to lay down the law on such matters for other people, and why I decline to accept for myself laws on such matters laid down by other people. But I must keep further discussion on this and other points for a future contribution to this "light" literature.

ANDREW PRINGLE.

ON LENSES.*

ASTIGMATION OR ASTIGMATISM.—If a cross be distinctly marked upon a card and focussed in the centre of the field of a lens, the two arms will be seen with equal distinctness. If now with an ordinary portrait lens the camera be swung round or tilted, so that the cross appears near the margin of the field, it will not be found possible to focus both arms of

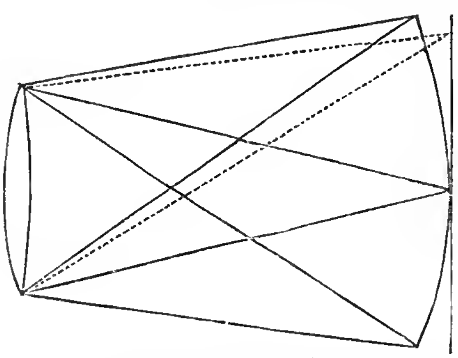
* Continued from page 261.

the cross at the same time. If that arm which is in a line with the diameter of the field be focussed the other will be wanting in sharpness. By turning the lens outwards, this other arm may be brought to a focus; but then the first one will be no longer distinct. The image of a point of light falling near the margin of the field of a lens possessing considerable astigmation, cannot be focussed sharply. On moving the lens it will be seen that the point takes the form of an oval or an approach to a short line, either in the direction of the diameter or the circumference of the field, accordingly as the lens is racked in or out. If a line happen to be in the same direction that the point is elongated, it appears sharp, but if the elongation be across the line the latter will be blurred. This characteristic is called "astigmatism" or "astigmation."

Distortion is caused by different portions of the lens, engaged in forming the various parts of an image, acting as prisms in bending aside the ray of light. Thus, with a single lens and a diaphragm at a distance from it, the axis of the ray coincident with the axis of the lens is not bent aside at all; but those rays coming from parts of the object towards the margin of the field, impinge upon portions of the lens possessing the form of a wedge or prism, and the nearer the margin the more this is the case. The images of those portions of the field are, therefore, turned aside, and, whether the stop be in front of the lens or behind it, proportionally more so the farther they are from the axis. Distortion is avoided by having an additional lens upon the other side of the diaphragm, giving a like amount of distortion, but in the contrary direction.

Curvature and Flatness of Field.—With an ordinary lens the focus of different parts of an image of equally-distant objects will be at something like the same distance from the lens, and to get them all sharp

FIG. 3.



Curvature and flatness of field.

at the same time, therefore, it would be necessary to employ, as the focussing-screen or the sensitive film, a portion of a sphere instead of a flat plate. When the oblique rays have their focus lengthened out, as shown in the dotted line, so as to fall upon a flat surface, the lens is said to have a flat field. Lenses corrected in any degree for this evil are said to be more or less flat-fielded. The great difficulty has been to get flatness of field without introducing an intolerable amount of astigmatism.

Absolute flatness of field must not be expected. The sacrifice of other good qualities in order to obtain this characteristic over any but a small portion of the centre of the plate is so great that, except with lenses where a very small diaphragm is used, it is only attempted approximately. It is, however, so valuable a quality that those lenses in which it has been made a particular point of are for most purposes to be preferred. It is, perhaps, the one quality to obtain which opticians would be justified in making greater sacrifices in other directions than they have generally been disposed to do. A lens may be examined for it in the following manner:—Focus some object sharply in the centre of the field; then swing the camera round so that the same object comes to points on the ground glass, at regularly-increasing distances of (say) one inch from the centre, and mark how much the lens has to be racked in at each distance. Now draw a straight line, and at distances upon it equal to those upon the ground glass, make uprights corresponding in length with the amount which the lens has had to be racked in at each distance, to get the best focus. Join the tops of these uprights by a line, which line will describe the curvature of field of the particular lens. This line should be compared both with the straight line from which it diverges, and with the circumference of a circle having a radius equal to the focus of the lens for the object that has been focussed. In order to reduce to an insignificant minimum any error arising from not having swung the camera accurately upon the optical centre of the lens, some distant object should be selected for focussing.

Flatness of field only implies the delineation upon a flat surface of objects at equal distances, and, therefore, even if absolutely attained, would still require, for even definition, that the various objects included should be placed in a semicircular curve round the lens, unless these objects were all so distant that the rays proceeding from them are indistinguishable from parallel ones. To delineate upon a flat field the image of a flat surface, such as a map or a newspaper, would require the marginal rays to be so much lengthened, that the field for parallel or distant rays would be actually curved the other way—that is, convex instead of concave.

By those unacquainted with the science of optics, curvature and flatness of field have often been confounded with spherical aberration and aplanatism; and, indeed, a diagram showing only the former characteristics, has actually been given by a professed teacher of the subject, in illustration of the word aplanatic.

Diffraction has been spoken of in connection with photographic optics. If it were really necessary to take it into consideration in the calculations for the construction of a photographic lens, these calculations would be even more complicated than they are at present. Fortunately this is not the case, and, as no scientific optician has admitted it as an element into such calculations, it may be dismissed.

When in January, 1839, Daguerre in France, and Fox Talbot in England, announced that they had succeeded in fixing the image of the camera, that instrument at once acquired an importance that could not otherwise have belonged to it. The lens with which it was furnished, although considered sufficient for a toy, or for occasional use to assist a draughtsman, had several characteristics which made its work as an instrument for the photographer very inferior to what a scientifically-designed instrument would give. Taking an ordinary double convex lens (say) of two inches diameter, and twelve inches focus, the following four faults had to be corrected:—1. Difference of the chemical and visual foci, necessitating an alteration or adjustment of the position of the plate, varying in amount with the distance of the object to be photographed, after each focussing. 2. Spherical aberration, in consequence of which the image was more or less confused and wanting in sharpness everywhere. 3. Curvature of the field, in consequence of which objects at equal distances, but upon different portions of the field, would be out of focus unless the plate were cup-shaped instead of flat. 4. Slowness of action.

The difference of chemical and visual foci could be corrected upon the lines already laid down. Daguerre himself, indeed, used an achromatised lens, but in England some of the earliest cameras were made for uncorrected lenses, and had graduations marked upon them for adjustment after focussing. The second mentioned fault—spherical aberration—was the most important, and the discovery of the remedy for this, involved the cure of the fourth defect, or that of slowness of action; because spherical aberration increases with the aperture of the lens—that is, with the proportion of the size of the lens to its focal length—so that a lens which was scarcely tolerable in its definition could not afford to have its rapidity increased by making it of larger aperture.

The want of a suitable lens being perceived, opticians and mathematicians in several countries set to work to try and cure the evils above-mentioned. One of these—Professor J. Petzval, of Vienna—succeeded in calculating the formula for an instrument which has always, and justly, been considered a triumph of mathematical science. So complete did it come into the world, that in more than forty years it is questionable whether any very important improvement or modification has been made upon it. This Petzval lens is the well-known portrait combination, which, with some little differences of detail amongst themselves, has been made by photographic opticians in all parts of the world. The essential and most striking characteristic of this lens is the elimination of spherical aberration, and the means by which this is achieved is, particularly, the separation of the components of the back combination. This separation allows the flint negative lens to possess so much *negative* spherical aberration as to correct the positive aberration of the whole system; and so perfectly is this accomplished, that it was possible to have the lens much larger in proportion to its focal length—quicker acting, that is—and, at the same time, give far finer definition than could be obtained with the then existing lenses, unless a very small stop had been used. The focus, at the same time, was somewhat lengthened towards the margins, so that the field, although not flat, was yet of a flatter curve, and did not for some distance on each side of the axis depart far from the flat plate.

By tolerating a certain amount of astigmatism it is possible to make the field of the lens flatter, and the amount of sacrifice that should be made of possible marginal definition to flatness of field, is a question upon which opticians have differed. I have said "possible marginal definition," meaning the definition that can be obtained towards the margin of the field if that part only be focussed; but in doing this with a lens of round field, the centre of the picture must be thrown much out of focus, or the subject to be photographed must be arranged in a deep curve. When this is done, owing to the violence of the perspective, all but the middle of the picture will appear exaggerated in size; and this effect is to be condemned, whether in the side figures of a group or, as it has sometimes been put forward in favour of a lens of round field, the advancing knees and hands of a sitting figure.

In some French portrait lenses of recent make, considerable flatness of field has been attained. The absolute definition has had to be a little sacrificed, but I think this sacrifice well worth making.

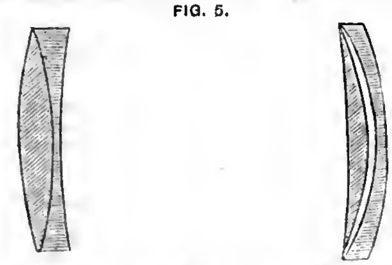
In the year 1866, the late Mr. J. H. Dallmeyer patented a variation of the Petzval lens. This variation consisted in reversing the elements of the back combination with such a modification of the curves as this change involves. The particular advantage claimed at the time for this form of lens has since been abandoned. The putting of the negative lens at the back allowed its distance from the positive element to be varied, and thus the perfection of its correction for spherical aberra-

FIG. 4.

Portrait Lens—Petzval's Original.

tion to be modified. It was stated that by altering the distance of the back lens, so as to reintroduce spherical aberration, and sacrifice definition at the focus, improved definition was obtained upon the planes not in focus. This claim—"diffusion of focus" it was called—was shown to

FIG. 5.



Portrait Lens—Dallmeyer's Modification.

be mistaken, and is no longer made. The lens, however, when employed with the elements in the position of best definition is a useful one, and some other well-known opticians have for some time past issued a series of lenses of this form. In this case, however, the back lenses are burnished together into their cell, and no shifting or alteration of their position is possible.

While on the subject of "diffusion" or "depth" of focus it may be remarked that a delusion on this point is cherished by a vast number of photographers. For this the manufacturing opticians are somewhat to blame. They have been in the habit of advertising lenses as having great "depth of focus," whereas that is a quality that, except as attained by the use of a small aperture or diaphragm involving slowness of action, does not exist at all. Still many photographers—careful, practical men, too, some of them—will tell you that they have, or have had, some particular portrait lens that will give the various parts of a sitter's head, the background behind him, and generally objects on different planes, with sharper definition than other lenses of similar aperture and focus, that have as fine or finer definition on any one plane. This is a curious case of mistaken observation; but in photography, unfortunately, mistaken observations may pass current as scientific facts.

Before passing on to the consideration of other lenses, it may be observed that some discussion has taken place as to which is entitled to be called a portrait lens. It is probable that portraits have, at some time or other, been taken by all the kinds of photographic lenses in existence. I have myself had in regular use a single lens for panel portraits and a lens of the rapid doublet, or Steinheil type, for promenades; but as the name "portrait lens" has been accepted as the distinguishing title for the Petzval intrument first described, and as the most striking characteristic of that instrument is that it will give good definition when used with an aperture of one-fourth of its focal length or even more, it would, perhaps, be best to retain the name portrait lens for a lens constructed on such principles that it may be made to work with that aperture. W. E. Debenham.

Practical Guide to Photography.

London: Marion & Co., Soho Square.

Messrs. Marion and Co. have published, under the above title, a useful hand-book of photography, which, without going deeply into the more abstruse branches, deals in a lucid and practical manner with the various operations connected with every department of the science. A short historical sketch is followed by a chapter on "The Application of Modern Photography," after which the working of wet and dry plates in and out of doors, printing, mounting, retouching, &c., are successively treated. Chapters on optics, on portraiture out of doors and in an ordinary room; instantaneous photography, printing-in skies, and combination printing; ferro-prussiate printing, and many other branches, deal with special subjects, and will prove useful to the novice. The work, consisting of upwards of two hundred pages, is handsomely got up and eminently practical.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 24th ult., the chair was taken by Mr. A. Cowan.

Mr. A. Mackie, referring to the lecture *On Lenses* given at the previous meeting, inquired what would be the effect, on the achromatising of a lens, of separating its elements—the crown and the flint—for any distance, or of having them in contact, but not cemented.

Mr. W. E. Debenham replied that altering the distances of the elements of a lens would to some extent alter its achromaticity, but much more so its correction for spherical aberration. Using the front elements of a portrait lens in contact, instead of being cemented, would not affect the achromaticity. There were advantages in the use of cement, as there was less loss from reflections, and, particularly, there was freedom from a deposit of dust, or of a film from exposure to the atmosphere. He had had a telescope of Dollond's, the image given by which appeared flat and misty. The objective was burnished into its cell, but upon turning away the brass rim, so as to be able to separate and clean the elements—there were three, a flint between two crowns—it gave a beautiful image. Lenses having uncemented internal surfaces ought never to be burnished in, but always set in screwed cells, so that they could be got at when required.

Mr. A. Haddon remarked that the glasses of telescope objectives were often set a certain distance apart. No doubt this was done with a view to more perfect correction of the spherical rather than the chromatic aberration. He then raised the question whether screwing a lens tightly into its mount would permanently deform the glass.

Mr. Debenham considered that with such a perfectly-elastic substance as glass permanent deformation would not result, but that it would return to its original form when the pressure was removed.

Mr. Haddon said that that was his view, but his reason for asking the question was that an optician had given as the reason for the defective working of an instrument which had been returned to him that the lens was permanently deformed from having been screwed down too tightly.

The Chairman remarked that whilst on the subject of lenses he would suggest that a table should be published giving the speed upon the uniform standard of diaphragms of various sizes with regard to lenses of different focal lengths. Perhaps Mr. Burton would undertake this.

Mr. W. K. Burton had already prepared such a table, giving the increase of diameter of diaphragm by the $\frac{1}{16}$ of an inch, and of focal length by half inches.

The Chairman then handed round a book and box for carrying sensitive plates. This will be found described in our last issue in the report of the meeting of the Photographic Society of Great Britain.

A question was read—Will an emulsion giving twenty on the sensitometer, if mixed with one of a lower number, give a mean between the two?

The Chairman believed that they would get the speed of the quicker. If there were much difference in the rapidity of the components—say ten or twenty times—the slower one would be unacted upon, and, as so much inert matter, would fix out, leaving the image thin. When they were nearly of the same speed the slower emulsion would be acted upon in the high lights, to which it would add force.

Mr. Burton knew of one commercial manufacturer whose practice it was to mix two emulsions—one a rapid one, prepared with ammonia, and giving a thin image; the other a stout-bodied one of about one-half the speed, prepared by boiling.

Mr. W. M. Ashman showed a sample of a bright lemon-coloured material for dark-room illumination, called "golden medium." Two or three thicknesses of this and two of green oiled silk, such as is sold at chemists' for surgical purposes, gave a light that was at once safe, sufficient, and pleasant.

Mr. Mackie said a few days since he had fitted the same material round a candle for developing purposes. He was at first afraid of the light, as it seemed too bright. However, he found that he continued development under the light for ten minutes without getting any veil or deposit upon a sensitive plate.

Mr. Hart had used a candle and ordinary orange paper, such as is used for collodion dark rooms. With plates giving twenty-four on the sensitometer the results were beautifully clear.

Mr. A. L. Henderson had the day previous substituted canary medium and yellow glass for the two ruby glasses that he had previously employed in his dark room. He found that with two minutes' exposure to his new light he only got a tenth part of the image that thirty seconds' exposure to the two rubies had given.

Mr. Barker thought that much depended upon the system of development. He had found that red light neutralised the effect of any white light that might be present. If a little ray of white light came sideways upon the plate whilst close to the ruby window the light of the latter was sufficient to prevent the white light from fogging the plate, as it would do if there were no red light to counteract it.

Mr. Debenham considered that this was a case of mistaken observation.

Mr. Burton said that we must either doubt our knowledge of the laws of nature or the accuracy of Mr. Barker's observation.

Mr. Haddon remarked that red light was not perfectly safe, and white light was not safe. The addition of the one to the other was not to be expected to produce a safe mixture.

Mr. Barker said that in his dark room, lighted by ruby glass, he could, when placing a plate of ruby glass over the developing dish, see the negative through the glass. In white light the ruby glass prevented his seeing the negative through it. Why was this?

Mr. Debenham replied that in a red light red objects appeared light like white. In his former dark room the red sides of pill boxes looked almost as light as the white tops. Red glass in such a case would not be very much more obstructive than white glass. In white light the eyes would be so filled by its superior power of illumination that they would not perceive clearly the light coming through the ruby glass—which light must pass it twice, once to illuminate the plate and then from the plate to the observer.

Mr. Henderson said that rapid plates would appear fogged in a ruby light when they were not so in reality, but would fix out clear. This was due to the fact that the more sensitive plates were composed of the green bromide of silver, which in a red light looked dark.

A discussion then took place as to the stage at which white light might be admitted to a dark room in which collodion was worked.

Mr. Henderson maintained that if it were intended to redevelope the plate white light must not be allowed to fall upon the plate even after thorough washing. Mr. Burton and Mr. J. Stuart, of Glasgow, took the opposite view.

As to the lighting of the dark room,

Mr. Stuart now used only yellow paper for all operations, including coating.

The Chairman referred to the death of the Rev. F. F. Statham, President of the South London Photographic Society, and stated, for the information of those who might wish to attend, the time and place of the funeral. On the motion of Mr. W. Ayres, seconded by Mr. Henderson, a letter of condolence was ordered to be written.

EDINBURGH PHOTOGRAPHIC SOCIETY.

"Round the World with a Camera" formed the subject of the Society's third lantern exhibition, which took place on Thursday, the 17th ultimo, in Queen-street Hall.

Mr. Andrew Pringle, who lately returned from a tour round the world, delivered the lecture, which was of a more than usually interesting character, as Mr. Pringle spoke from the results of his own experience. The views exhibited were derived from negatives taken by Mr. Pringle in the varied countries through which he travelled.

As the transparencies were of a very high order, the views, illustrating so many lands, were put on the screen in the most effective manner. The frequent applause of the audience sufficiently testified to their complete satisfaction.

A vote of thanks was awarded to Mr. Pringle for his lecture and admirable illustrations.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of this Society was held at the Free Library, on Thursday, the 24th ultimo,—Dr. Kenyon, President, in the chair.

The minutes of the March meeting were read and confirmed, and Mr. C. Harris was elected a member.

The Chairman announced the donation of two lantern slides for the library, and eight prints of views near Settle for the album, from Mr. Watts. He (the Chairman) stated that with reference to a passage in his introductory address suggesting the desirability of a dark slide made with the shutter to open inside the camera—in place of the usual drawn-out shutter, which was too familiar in commerce—he had received a letter from Mr. S. Sidey, of London, stating that he had constructed two such slides about three years ago, never having seen or heard of one before; he had used them ever since, and offered to send one for the Society to examine. The Chairman gladly accepted the offer, and had the pleasure of exhibiting the slide. The mechanism, it would be observed, was beautifully simple and most ingenious. A slide of this kind would be most useful in instantaneous work, and wherever it was desirable to have the camera as inconspicuous as possible. The shutter exhibited was lighter and more compact than the ordinary form. Its use presented less leverage to the wind and less chance of admission of light during exposure. The plate was uncovered far more easily than by drawing a shutter. A rigid camera might be carried ready focussed, and with this slide exposure could be readily effected without anyone knowing what was going on. He (the Chairman) proposed a cordial vote of thanks to Mr. Sidey for his kindness in sending this interesting exhibit.

Mr. J. Thomson (21, High Park-street, Liverpool) exhibited and explained a new stand of his invention. The main features of this new stand consisted of stays for the purpose of steadying a large camera, and a very ingenious compass-swing arrangement for instantaneous work at sea, enabling pictures to be taken when the rolling and pitching of the vessel would otherwise render photography impossible.

Mr. H. N. Atkins recounted his last bank-holiday experience, when he found an excellent substitute for a focussing-glass in a film of gelatine which had had some milk added to it before it had set.

The Rev. H. J. Palmer corroborated Mr. Atkins' experience, and said that five years ago he had read a paper in that room recommending the gelatine-milk film as a substitute for ground glass.

Mr. Cornish exhibited a new stand of startling novelty. When in use it was rigid and strong, and when not in use it could easily be stowed away in the pocket. Each leg was composed of a ribbon of brass, which was rolled and extended on the principle of a paper spill-lighter. In answer to numerous questions, Mr. Cornish stated that it took from five to ten minutes to put up; its cost was 25s. It was admirably adapted for cyclist-photographers. Messrs. Newton and Co. were the agents for its sale.

The Chairman showed and described a new camera by Hare, which contained several novel features, and had been made especially for the tricycle.

Mr. J. H. Ellerbeck opened the discussion upon the subject appointed for the evening, namely, *The Best Mode of Developing Instantaneous Negatives.* He thought that among the essentials for success in this department of photography were slow development and the use of less pyro. than usual.

Mr. R. Crowe said that there were three classes of instantaneous subjects:—1. Open sea pictures with but little contrast. 2. Street views. 3. Lake scenes, and subjects with deep shadows. His formula for instantaneous work was one ounce of ammonia to two ounces of water, with sixty grains of bromide of potassium. For pictures in class 1 he would use a double quantity of pyro. and double bromide, in order to increase the contrasts. For class 2 three grains of pyro. to the ounce, and the usual proportion of bromide. For class 3 less pyro. than usual, care being taken not to force development and so produce fog.

The Chairman asked Mr. Crowe the lens and aperture with which he usually worked.

Mr. Crowe replied that he used a Steinheil lens of eight and a-half inches focus, and an aperture of $\frac{f}{}$.

Mr. W. H. Kirkby asked for further detail as to development.

Mr. Crowe said that the plate should be placed in pyro. solution first, and then the ammonia and bromide added twenty drops at once, and as soon as discolouration took place developing should be stopped.

Mr. Ellerbeck recommended keeping bromide and ammonium solution in separate bottles. By using bromide and pyro. first, and then adding ammonia, there would be greater likelihood of clean pictures.

Mr. Kirkby preferred to begin developing with plain pyro., and then to add ammonium and bromide.

The Rev. H. J. Palmer invariably gave a preliminary soaking in very weak solution of bromide of potassium.

Mr. Watts, on the other hand, strongly advocated first soaking in water with a few drops of ammonium, and then adding pyro. and bromide.

The Hon. Secretary suggested that as the discussion was an important one it should be deferred to the May meeting, and be opened by Mr. Watts.

Mr. Ellerbeck showed some prints from negatives recently taken at Hawarden.

The Rev. H. J. Palmer produced an excellent developing lamp made from a Chinese lantern, and rendered non-actinic by Thomas's ruby varnish.

After the usual votes of thanks to the exhibitors had been accorded the meeting was adjourned.

Correspondence.

Special Meeting of the Photographic Society of France.

An extraordinary and special meeting of the Photographic Society of France was held on Friday last, the 25th ult., in order that M. Audra might fully develope and demonstrate his plan of making gelatino-bromide of silver emulsions.

I may call it an "extraordinary meeting," as the idea is an innovation, it being the first time that the Society has thought fit to convoke its members for such an object. The crowd of members and friends present afforded a proof that this innovation should be repeated, or that the gelatino-bromide of silver process is in appearance more simple than in reality, and therefore numbers came to seek for information.

M. Audra is well known to the readers of The British Journal of Photography as an enlightened and intelligent amateur—in fact, one of the many to whom we owe the present advanced state of photography. I will endeavour to repeat his demonstration as clearly as possible—not that there is anything new in his formula or secret "dodges" in his manipulation, but because there is a simplicity in his manner of working which I myself have never before seen, and which I am certain will draw many adepts into this interesting field of our art-science.

M. Audra had before him on the table only a very few objects—those, in fact, indispensable for the demonstration. He began his lecture by saying that the system he recommended for emulsion making was simple in the extreme, at the same time that it did not give the palm to any other either in rapidity or perfection of results, it being the fruit of three years of incessant study and experiment.

The object this evening (he said) is to obtain a silver salt incorporated with gelatine, and that in the form of an emulsion. To obtain this result I introduce into a glass bottle holding about a pint—

Gelatine (Nelson's No. 1)	4 parts,
Distilled water	200 ,,
Ammonium bromide	20 ,,

This bottle is now placed in a kettle and the water warmed sufficiently to dissolve the contents. When the gelatine is dissolved the bottle is taken out and allowed to cool down. The following solution is then poured in:—

Water	50 parts.
Ammonia	15 ,,
Alcohol	50 ,,

I now dissolve in a glass beaker—

Distilled water	100 parts.
Silver nitrate	30 ,,

When the silver nitrate is thoroughly dissolved I put a glass funnel into the neck of the bottle containing the aqueous solution of bromide. This I give a whisk round, set the recipient upon the table, and pour the silver solution into the funnel without any precaution whatever, and that in full gaslight. I whisk it round once or twice. The silver bromide can now be seen to be of a bright ruby colour, and it will remain so for an hour or two. The emulsion in this state is to be kept twenty-four hours to ripen (without heat).

I will suppose the twenty-four hours to have passed away. I now weigh out twenty parts of hard gelatine, which, being slightly moistened, I put into the bottle and stir it well with a glass rod. If any silver bromide has been precipitated this gelatine will act as a mop and break it up. I now put the bottle into cold water, and raise the temperature until the gelatine is dissolved. The silver bromide has now a bright blue colour, and has gained its maximum of rapidity. I then pour out the emulsion into a porcelain tray and leave it to set. Generally in the morning it is hard enough to be cut up to be washed.

M. Audra then took a tray containing a jelly of gelatino-bromide of silver, and with a silver spoon he cut it into small square pieces ready to be forced through his canvas in order to wash away all soluble salts. He informed the members that up to this point all the manipulations can be carried on in white light and without any fear of fogging the emulsion, as the excess of ammonium bromide sufficed to prevent the action of light upon the emulsion.

I had here the privilege of putting several questions to M. Audra on the deoxidising influence of bichromate of potash, which he recommended to be used. His reply was that he had found no necessity to use the bichromate of potash, as his experiments had convinced him that the free bromide in the emulsion permitted the use of white light in the manipulation up to washing, and that with impunity.

Here are two excellent things which M. Audra has taught us:—1. That an emulsion need not be shaken or stirred to death by complicated apparatus.—2. That white light may be let into the dark room with impunity during the mixing or formation of the silver bromide, and to the great comfort and convenience of the manfacturer. Can this be depended upon? Let us see by a simple rule of three how much free bromide M. Audra has in his emulsion.

The equivalent of nitrate of silver being 170, that of bromide of ammonium 98, we state the problem as follows:—As 170 : 98 :: 30 : 17·3. Therefore, as M. Audra employs twenty parts of bromide of ammonium he has but 2·7 parts of free bromide in his emulsion. In my ordinary work I use more than this, and as soon as an emulsion is made it is my custom to pour a band upon a glass plate and expose half of it to gaslight in order to detect fog. When a dense black is obtained and the white remains pure it is set aside as good; if a sign of fog show itself, more bichromate is immediately added to cure it. I lay stress upon these facts in order that some discretion may be used, and to prevent, if possible, a beginner from making an emulsion in full sunlight. I am myself convinced that so small a quantity of free bromide cannot render the emulsion insensitive to white light in excess. This digression explained, we will return to the lecturer.

M. Audra, in reply to a question as to the addition of iodide, informed the members that he preferred pure bromide; but, if iodide be used, it should not be in greater quantity than one-fiftieth of the bromide employed. It can be added to the jelly about one hour after the emulsion is made.

M. Audra then put the small pieces of gelatine into a piece of canvas, and squeezed it through under water. This he did three times. When thoroughly washed he added thirty parts of swelled gelatine, dissolved by a gentle heat, filtered, and showed how to coat plates. He expressed an opinion that excessive filtering was not necessary. He himself only filtered through medical cotton—a kind of cotton which, if put into a glass of water, will sink to the bottom immediately.

As soon as the plates prepared by M. Audra were set he put them into a kind of square box devoid of top and bottom. Each box contained one dozen plates, and so made that they fit one upon the other, and so form a kind of chimney. He said that the drying was slow, but devoid of drying-marks, &c. He rubbed the plates over with a two-per-cent. solution of silicate of potash before preparing them. This chemical permitted the emulsion to run over it similar to collodion. No glass rod was used, and frilling was unknown.

M. Audra was highly applauded, and a desire was manifested that this interesting demonstration would be succeeded by others. A hope was expressed that the next demonstration would be given by Mr. A. L. Henderson, whose appearance is eagerly looked for by all lovers of photography. E. Stebbing, *Prof.*

25, *Rue des Apennins, Paris, April* 29, 1884.

LONG-FOCUS LENSES.

To the Editors.

Gentlemen,—This subject has recently been treated in your columns with special reference to portraits. Perhaps a few remarks on the use of a telescope object-glass as a photographic lens of long focus may prove interesting.

I have adapted the object-glass of a three-inch telescope of the cheap form, so largely sold for about £5. Its focal length is forty-four inches, and its form plano-convex. I have mounted it in a cell, with a fixed diaphragm 2·3 inches in diameter placed four inches in front of the lens, the plane surface of the latter being in front next the diaphragm. I use this lens with a 12 × 10 camera with the aid of a light pyramidal wooden tube, the large open end of which fits over the front frame of the camera (the sliding front having been removed), and is secured behind it by brass "buttons." The flange for the lens is screwed on to a block filling the small (truncated) end of the pyramid. Near the front end of the latter a U-shaped stirrup of brass is fixed on the under side of the tube, and has a tapped hole in the centre of it. This is to support the long, overhanging tube, thus:—The 12 × 10 camera is mounted on its tripod, the pyramid and lens fixed, and the object focussed. A small tripod is then brought up under the stirrup, and fastened to it by its own screw, which works in the tapped hole mentioned above. The camera is thus supported on six legs, and is extremely rigid, both in high winds and under the shock of a drop-shutter.

It will be seen that the ratio of aperture to focus is $\frac{1}{19}$. This stop gives sharp marginal definition on a 12 × 10 plate, and would cover much larger plates with smaller stops, or if, as in portraits, microscopic definition were not required at the edges. I have taken very good portraits in a room with ordinary side light with fifteen to twenty seconds' exposure. The depth of focus is very satisfactory. For landscapes of the "instantaneous" class, a drop-shutter giving $\frac{1}{14}$th of a second effective exposure suffices.

There are several uses, besides that of taking large portraits, for which a lens of this abnormally-long focus is available. There are numerous views which can only be taken from a point so distant that a negative taken with an ordinary lens would have to be enlarged. I have also used it for taking instantaneous views of children, &c., from my window. Of course it is quite necessary to be unobserved in such cases, otherwise the figures immediately range themselves in a perfectly-straight line and stare at the camera. With my lens not only can figures be taken of a good size at a considerable distance—a five-feet figure fifty yards off comes out one and a-half inch high—but the angle of view is so small that the camera can be placed far within the room and quite out of sight.

Shipping is another subject where it is very often desirable to obtain distant objects on a larger scale than is ordinarily practicable. I have recently been instructed to take a view embracing a very small angle from a given position at sea. Having moored a vessel on the required station, I was enabled with the 44-inch lens to take a very good view of the required bit of coast, although the motion of the vessel was considerable. The conditions were trying for a lens of such long focus, as an angular motion of the vessel of only one minute during exposure would cause the image of a fixed object on the plate to move about $\frac{1}{80}$th of an inch; but by dropping the shutter at the moment when the vessel was stationary at the top or bottom of a pitch I have reduced the width of blur to much less than this—perhaps $\frac{1}{500}$th of an inch. The lens seems to answer equally well reversed; that is, with the stop behind, the plane face being, of course, still towards the stop. The angle is too small for any trace of distortion, either barrel or pincushion, to be visible.

In conclusion: I would direct attention to the very small cost at which such a lens may be fitted up. A suitable object-glass costs about 50s., but one may often be procured from the telescope-maker slightly chipped, so as not to be available for a new telescope, but practically as good for photography. The cost of this would probably be about one pound. The mount and the extension of the camera need not cost more than another pound, and the latter is very useful for enlarging purposes. It might be made portable with a little more trouble.—I am, yours, &c.,

April 28, 1884. R. F. W.

THE ADJUSTABLE SKY-SHADE.

To the Editors.

Gentlemen,—In a footnote which you append to Dr. Nicol's article in the last number of the Journal (April 25th) on my sky-shade, you say you "are a little in doubt as to who was really the first of those *whose claims to the paternity*" of shades on this principle "are before the world."

This conveys the impression that I am among the number of those who make this claim; and, as there is nothing more repugnant to me than claiming merit belonging to another, I will esteem it a favour if you will refer to the number of your Journal for November 9th, 1883, in which Mr. Norman Macbeth's article, descriptive of my shade, appeared, and where, by my request, he very fully states the sources from which I got the suggestion to have been your Journal for November 5th, 1875, and your ALMANAC for 1876. In the former the Rev. Canon Beechy described what he called a "split sky-shade," and in the latter Mr. Baynham Jones wrought out the idea more fully. Both of these contain the suggestion or "generic idea" of mine, and they were fully acknowledged.

All that I claim is that, while fully admitting my indebtedness to these gentlemen for the merit of the suggestion, I have put the application of it into a much more practicable form; and a glance at their diagrams in the two communications above quoted, and to your number for November 9th, 1883, in which mine is given, will, I think, sufficiently show this. Had you referred to the article describing mine, your footnote, if given at all, would, I believe, have been differently expressed.—I am, yours, &c.,

89, West Regent Street, Glasgow, April 29, 1884. JOHN PARKER.

[Since writing the footnote to which Mr. Parker refers, and which was not intended to convey anything approaching to an insinuation that he had made, or was capable of making, a false claim to the invention of the sky-shade, we are now able to give its early history. The shade, which was for a considerable period on exhibition at this office—not nineteen, as we inadvertently put it, but fourteen, years ago—was invented by Mr. W. H. Price, and at page 24 of our issue for January 21st., 1870, it will be found described, together with an engraving showing its formation. But Mr. Price, although a genuine inventor, was not the *first* to invent this shade; for, upon the publication of the article just referred to, it then transpired that it had been not only invented but patented in 1862 by Mr. J. Mann, of Bruce Castle Academy, who illustrated his specification by drawings, one of which was similar to that by which Mr. Price's subsequent invention, and the subsequent independent inventions of several other gentlemen, were illustrated.—EDS.]

ENAMELS.

To the EDITORS.

GENTLEMEN,—In answer to Mr. F. Dugon: why does he make excuses and call them difficulties? As he is anxious to take up the gauntlet, allow me to make it worth his while by increasing the stakes fivefold—*yourselves* as referees.

I am sure I shall not be alone in thanking "B. F." for his very interesting information. Whatever Mr. F. Dugon's abilities may be, it is well his relationship and position should be known.

But why a complaint from Mr. A. L. Henderson? He seems to take to himself a cause for displaying his strong feeling towards me. What can I have said to sting *him!* Mr. Henderson would do well to read my original statement carefully, and expound it wisely to Mr. Dugon. If the Editors endorse "B. F.'s" invitation, I will with pleasure give a practical article on the enamel process as worked by myself.—I am, yours, &c.,

Rembrandt Studio, Redhill, April 28, 1884. J. BERRYMAN.

[It will afford us pleasure to receive the "practical article" proposed by Mr. Berryman.—EDS.]

To the EDITORS.

GENTLEMEN,—Your correspondent "B. F.," writing on *Photo-Enamels*, "thinks it is scarcely ingenuous, being a relative of, and assistant to, a well-known skilful photo-enameller, for me," &c. I beg to state that I am certainly in the employ of the photo-enameller referred to, but am not assistant to him in his capacity of photo-enameller, my occupation being entirely different, so that the "high vantage ground occupied by Mr. F. Dugon in this connection," mentioned in the Editors' remark, does not apply. I knew nothing whatever of the enamel process until last November, when I witnessed a demonstration, which was afterwards repeated at the London and Provincial Photographic Association.

After perusing the above I think your readers will agree with me that I am perfectly justified in attributing any knowledge I possess to the fact of my having witnessed the said demonstration.—I am, yours, &c.,

April 29, 1884. F. DUGON.

[With the publication of the above here ends the matter, so far as its polemic aspects are concerned.—EDS.]

GELATINE NEGATIVES.

To the EDITORS.

GENTLEMEN,—If you think the matter of sufficient importance you might allow me to correct a small error into which "Free Lance" has fallen as to remarks made by me at one of our society meetings.

In the first place: I do not think that "Free Lance" should "tilt" at remarks unless he has been furnished with a *full* report of what had been said on the subject. Matters reported "verbatim" are fair "game" for him, but not surely the short reports of meetings held, which often contain no more than a mere indication of what was the subject in hand.

I never said that "every negative had to be intensified;" on the contrary, I pointed out that if the action of the ammonia were continued long enough the colour of the negative seemed to be changed without adding to the apparent density at all, and that in my opinion detail too transparent, or of bad printing quality, was brought up to its proper power by this proceeding without in the least over-burdening the high lights. Of course this is only my opinion. If "Free Lance" considers the gelatine negative all that could be desired, so much the better for him. I hold another opinion.

Now and again, when the subject is entirely suitable, gelatine produces admirable work (after its own style); but I confess that I am sick of the great bulk of gelatine work, and think it a rare treat to come upon a photograph taken in the old days of wet plates. "Free Lance" considers that "gelatino-bromide would not be worth having if every negative had to be intensified." This, of course, is a mere figure of speech, as no doubt "Free Lance," like the rest of us, would not grudge the extra work were he assured that his work was improved thereby.—I am, yours, &c.,

Dundee, April 28, 1884. J. K. TULLOCH, M.B.

THE NEW DEVELOPER.

To the EDITORS.

GENTLEMEN,—I have tried the new developer, described in an editorial article of your last issue, and got very good results. In one instance development was prolonged over three hours, but no stain; nor was there any frilling, although I often experience this from the same make of plates when development is at all prolonged.

I anxiously await further results, and am sanguine enough to hope that at last a developer is forthcoming that will allow the much-desired latitude in exposure.—I am, yours, &c., J. BATE.

April 29, 1884.

PHOTOGRAPHIC SOCIETY OF IRELAND.

To the EDITORS.

GENTLEMEN,—In the report of the meeting of the above Society held on the 18th inst., the name of Mr. G. Pim, who exhibited specimens of Willesden paper and drew attention to the various uses this paper may be put to for dishes, trays, &c., was omitted. I would be obliged by your noting this correction.—I am yours, &c., CHAS. W. WATSON,

Asst. Hon. Secretary.

Dublin, April 28, 1884.

ACTINISM AND WAVE-LENGTHS.

To the EDITORS.

GENTLEMEN,—Referring to your foot-note to my article in last week's issue, you state that your columns are kept open for the purpose of discussing matters of practical photographic interest. If you did not think my articles were such why did you publish them?

As to my statement—"that it is useless to use two or more thicknesses of ruby glass, because the light which had passed through one would pass through the other unchanged, and that the action of the second thickness would be to simply cut off the power of the light, and for this purpose ground glass or white tissue paper would answer equally well"—it is most singular that in the interesting article by Mr. W. H. Harrison on the next page he expresses the same idea in nearly the same words. He there says:—"Under no circumstances should two coloured screens of the same material be used in the window of one lantern. The first coloured screen has filtered out all the actinic rays it had the power to absorb, so a second one of the same material can do little more by its colour; consequently its presence, practically speaking, but darkens the room, and has little influence but that of injuring the eyesight of the operator." Your readers will see that Mr. Harrison's experiments fully corroborate my statement, or, rather, what you are pleased to term "one of my illogical arguments."

As to the superposition of any two colours which produce white light: you say the safety would be undoubted, if safety can be the necessary accompaniment of absolute darkness. How can any two colours (supposing, as I stated, that they could be obtained pure) *producing white light* produce absolute darkness? It is unfortunate that you should make such a mistake as to say that absolute darkness was produced when glass screens were used. For instance, if you take a piece of so-called "cathedral green" of a yellowish-green tint and put it in front of one sheet of ruby glass absolute darkness is not produced; in fact the light passing through them is brighter than that passing through two thicknesses of ruby glass. But there are other ways of using the two colours. I thought of applying the idea to my reflecting lamp; and it is a strange coincidence that in Mr. Harrison's article he proposes to use two lanterns for the same purpose. I still contend if we can obtain pure colours that the white light produced by the superposition of red and yellowish-green would be the safest for photographic purposes, because (if I may be allowed to quote one more authority, namely, Mr. Lewis Wright, in his work on *Light*, published in 1882) "we may have a white light undistinguishable by the eye from any other white light, which will not, on prismatic analysis, yield more than two colours." And of the visible spectrum the two colours I proposed, which have the longest wave-length of any two which do produce white light, must be the best for photographic purposes.

I have read (and, perhaps, carefully studied) several acknowledged text-books on *Light* and *Colour*, and have never seen any mention of the fact that characters written in red ink on white paper, when viewed through glass of the same colour, are invisible, or any experiments of a similar kind which you say were familiar to every schoolboy of the past generation. I should feel obliged if you would say in what text-book it is mentioned, as the only experiment I ever remember seeing, at all bearing on the subject, was one mentioned by Prof. Tyndall, who said that Mr. Woodbury discovered that on looking through a piece of blue glass at green leaves in sunshine the light which came from the body of the leaves was crimson. This was probably due to the chlorophyll in the leaves.

As to my theories:—1. That there are two opposing forces in light, namely, that which produces the long wave-length or heat power *versus* that force producing the greatest actinic action.—2. The action of light on a film, namely, the bursting of the cells of the gelatine through the expansion or other action of the particles of silver bromide when acted on by light.—3. That light in passing through coloured glass or other medium is brought to one wave-length or rate of vibration, instead of all colours but the one being absorbed or annihilated: I can leave these for the present, knowing, as I do, that they have started new trains of thought in the minds of several of our leading experimentalists.

In a conversation, a short time since, with a gentleman who was selected a few years ago as one of the Cantor lecturers on photography at the Society of Arts (so I suppose we may consider him an authority), he said there was probably a great deal in my theory of the action of light on a film, as it would explain several difficulties, such as the effect of friction on a plate, the action of bichromate of potassium on an exposed plate, &c.; and we went into the question as to whether the microscope could not be used for further experiments on the subject. Only this morning I received a very sympathetic and encouraging letter from one of the old members of the Photographic Club, who had seen your foot note to my article.—I am, yours, &c., HERBERT S. STARNES.

April 28, 1884.

[As Mr. Starnes' article formed a chapter in an established discussion, it was not our place to decide that he was in the wrong; hence the appearance of his article. We have a right, however, to differ from him, and to declare our points of difference, which we did. A further explanation will be found in an editorial article on page 275.—EDS.]

Notes and Queries.

"AJAX" writes:—"With reference to 'S. T. W.'s' query in last week's Journal, I mean that the cake of emulsion which will be found at the bottom of the vessel (containing the methylated spirit into which the emulsion is poured to eliminate the salts) should, only for keeping to any future time, be placed in the glycerine, alcohol, and thymol."

"Do you know how the famous Pellet paper is prepared? If you do, will you give me the information? I refer to the paper by which, when copying from an architect's drawing, blue lines are produced upon white paper, and a specimen of which class of work I enclose.—Yours, &c., ARCHITECT."——In reply: The formula by which M. Pellet prepared his paper originally was as follows:—

Oxalic acid	154 grains.
Perchloride of iron	308 ,,
Water	7 ounces.

Those who have tried this process say that the quality of the drawings is improved by mixing a little gelatine with the above sensitising solution. We have not heard of M. Pellet having modified or altered this formula.

I NOTICE that nearly all the good landscape or architectural photographs that it has been my privilege to see were taken, or have the effect of having been taken, in bright sunshine. Is it necessary always, to obtain this effect, that there should be actual sunshine, and may fair results be obtained in actual shade? Presuming that a village street runs direct east and west, the principal houses being on the north side, what should be a suitable time to photograph, and what are the rules for obtaining the best effects in street photography? Could you not favour your inexperienced readers with a series of articles on outdoor photography? We shall have to pay for learning, but you may abridge the cost.—B. B."——In reply: To obtain a photograph of the village street that shall combine softness with boldness of effect, as regards light and shade, let the exposure be made when the sun is partially shaded by light clouds.

S. BARRY inquires if we can furnish him with a means of preparing an extremely fusible alloy in the composition of which there is no mercury. ——In reply: We are aware of one that was discovered a few years ago, and which will melt at a temperature below that requisite to boil alcohol. It is, so far as we know, the most fusible metallic compound without mercury that has been published up to the present time. Melt together—

Bismuth	14 parts.
Lead	8 ,,
Tin	6 ,,
Cadmium	2 ,,

To test its great solubility, place a few lumps of this alloy in a test tube, and pour in sufficient alcohol to more than cover it. Then hold it over the flame of a spirit lamp, and the alloy will be seen to fuse and remain at the bottom as a molten mass, while, as yet, the alcohol has not commenced to boil.

THE REV. FRANCIS JOHNSTON says:—"After reading your article on *Polarised Light* I attempted to adapt a Nicol prism to my camera lens, but found it quite useless for all but axial rays. This is, doubtless, owing to some shortcoming in the prism employed; for I have heard of, although I have never seen, prisms capable of transmitting an oblique ray, and which might, therefore, be entitled to be designated 'wide-angle prisms.' A friend who is at present residing with me speaks of the existence of a fluid Nicol prism, by which it is possible to transmit a much wider angle of light than can be done by means of one formed of calcite; but none of our local opticians seem to know anything concerning either its construction or capabilities. Can you throw any light upon this matter? The great advantages of a fluid polarising prism will be obvious to any one who has given the subject consideration."——In reply: The only prism which at all answers the description here given is one devised by M. Jamin, of Paris. It consists of a cylindrical vessel—such as a tube of brass—having glass ends, and filled with bisulphide of carbon, a thin slice of Iceland spar being placed obliquely in the fluid. This is the only fluid polarising prism of which we are aware, and we have no doubt of its capability of transmitting a wide angle of light. But this can also be effected by means of a large solid prism of spar—not wide, be it understood, in the same sense as that in which we speak of an angle of view of a landscape, but as applied to polarisation of light.

G. G. B. says:—"I had a wide-angle doublet, by a late London maker, bequeathed to me, and upon examining it I find that it does not include a wide angle, but, on the contrary, a very narrow one. The back lens is tolerably close to the rotating diaphragms, but the front lens is three times the distance of the other from it. Is there not something wrong here?"——In reply: Of course there *is* something wrong. It will be found that upon unscrewing the front lens a wide ring, the same diameter as the mount, interposes between the lens and the mount. Unscrew this and lay it aside, as it has nothing to do with the objective when used in its complete form. It is only when the front lens is to be used alone as a single landscape combination that the ring in question—the width of which varies from half-an-inch to an inch according to the dimensions of the lens—is to be employed, its function consisting in keeping the lens at a greater distance from the diaphragm than when it is used as an element in the wide-angle doublet.

"GENTLEMEN,—It has always been said that carbon photographs were durable, and that, while there was every probability of silver prints fading with more or less rapidity, photographs in carbon were beyond suspicion. In the face of this I have most positively to assert that a print of this kind in my possession has faded, or, more correctly, that its whites have become discoloured. I have the most ample means of verifying this; for when the print was placed in a frame a piece of white paper, upon which was written a brief announcement respecting the individual (deceased), of whom it was a portrait, was of precisely the same degree of purity as the whites of the portrait. This paper is still white, but the whites of the photograph have become greatly deteriorated. This being so—and that it is the case is palpable to all who examine it—it is evident that carbon photographs must be dethroned and removed from the position which has been erroneously accorded to them.—THOMAS BLACK."——In reply: Our reverend friend is perhaps not aware that the evil of which he complains has been recognised for many years. It arises (or *arose*, seeing it is now a thing of the past) from a certain peculiarity in the manufacture of the paper itself, and has nothing whatever to do with the kind of photograph which happened to be printed upon a sample of such manufacture. The paper itself would have become discoloured even although no photograph, whether in carbon or silver, had been printed upon it; but when representations were made to the papermakers they adopted such precautions as ensured the eradication of the evil. We are justified in saying that, if the final transfer paper for carbon printing be obtained from a responsible firm acquainted with the requirements of the process, not the slightest suspicion need attach to the permanence of the prints.

Y. Z. says:—"In making enlargements on wet collodion by means strictly analogous to the now nearly-forgotten photo-crayon system of the late Mr. Oliver Sarony, although I get, in nearly every instance, the class of tone at which I aim I cannot get rid of a certain heaviness in the lights. Not only does a species of haze cover the highest lights, but there is a want of delicacy in the half-tones. This appearance is not observed when examining the enlargement as a transparency, but it is painfully apparent as soon as the photograph receives its paper backing. It would be considered a special favour if you would give me a few hints as to the cause of this appearance."——In reply: The collodion employed is unsuitable. In this class of work special caution must be taken to secure cleanness throughout, with the most absolute transparence in the high lights. In not one case in a hundred can this be accomplished when using negative collodion. The best way of employing ordinary negative collodion for this purpose is to reduce the proportion of salting material present by adding at least one-fourth of its volume of plain collodion. Then dilute this by the addition of a mixture of equal parts of ether and alcohol, the precise quantity of this diluent having to be determined by the thickness of the collodion. Sufficient tincture of iodine (iodine dissolved in alcohol) must now be added until it is of a deep sherry colour. The collodion is then fit for use, but the strength of the silver bath must be reduced in a proportionate degree. Make use of a pyrogallic acid developer containing a fair proportion of citric and acetic acid, and if ordinary care have been taken to prevent light from obtaining access to the plate the result will be a perfect enlargement—pure in the whites, and transparent not merely in the delicate half-tones, but in the deep shadows. We are pleased to find that this convenient and effective method of producing enlargements is practised by at least one of our readers.

I will exchange a good photographic studio, show-case, balustrade, pedestal, and other accessories for a cottage piano of good make.—Address, L. W. Green, 18, Dennett's-road, Peckham, S.E.

I have several large oleographs (*Devotion*, and others larger), handsomely framed, which I will exchange for anything useful in photography.—Address, W. Slater, 282, Albany-road, Camberwell.

Wanted, two good interior and exterior backgrounds—Seavey's preferred; also imitation rock-work. To exchange, a new gem camera, with nine lenses.—Address, G. P. Abraham, Photographer, Keswick.

Wanted, a symmetrical or rapid doublet, in exchange for an extremely portable 11 × 6 landscape camera, by Meagher, stereo. arrangement, carriers, two single slides, &c.—Address, H. C., 3, The Grove, Vauxhall Bridge, S.W.

I have for exchange a large oil paint box, fitted complete, by Windsor and Newton, which cost £5 5s., and hardly used; also, electric bell, by the British Insulite Company. Offers requested.—Address, F. S. Lyddon, 2, Oakland Villas, Redland, Bristol.

My 5D being too heavy for outdoor camera, I will exchange it for a 12 × 10 rapid symmetrical or size larger: cash adjustment. What offers for a splendid hand-pushing van for plates 15 × 12?—Address, John Hodge, 31, Union-street, Stonehouse, Devon.

I will exchange whole-plate portrait lens by Jamin and Darlot, which will take 12 × 10 views, with centre glass, and Dallmeyer's No. 2B patent *carte* lens. Wanted, Dallmeyer's or Ross's 12 × 10 patent group lens.—Address, 17, Sneyd-street, Tunstall, Staffordshire.

I will exchange a Watson and Son's whole-plate universal studio camera, in perfect condition, with all recent improvements, including the double-swing back, for a tourist's dry-plate camera, about half-plate size, with three backs.—Address, Thomas Coan, 93, Caledonian-road, King's Cross, N.

Photographic studio, 18 × 9 feet, with dark-room and printing-room attached, two washing troughs, oilcloth on floor, backgrounds, and accessories, in exchange for astronomical observatory. Photograph and scale tracing for twelve stamps.—Address, W. I. C., 22, Victoria Crescent, Eccles, Manchester.

I will exchange Dr. Liesegang's *Manual of the Carbon Process*, Abney's *Photography with Emulsions*, and Lake Price's *Photographic Manipulation*, for other books. Wanted, Wake's *Manual of Colouring*, Chadwick's *Magic Lantern*, and Lewis Wright's *Light*.—Address, W. J., 2, York-street, Covent-garden, London, W.C.

What offers for large porcelain dish, 14 × 12, depth two inches; ditto large bath, to take 10 × 8 plates; quarter-plate box, to hold six dozen and six plates; small victoria camera, repeating back slide; and three slips of cottage scenery, 7 × 3 feet? Wanted, a half-plate lens or a pair of stereo. lens, or offers.—Address, S. Sidey, 419, Kingsland-road, E.

I will exchange an excellent camera and lens, all complete and in good condition, takes portraits or views 9 × 7, 8½ × 6½, and smaller sizes, with five carriers, honestly worth £6, for a short-focus for groups 10 × 8 (must be good) interior or exterior backgrounds, or serviceable head-rest, &c.—Address, Principal, Berlin Photographic Company, 160, Victoria-road, Aldershot.

I will exchange a complete set of photographic apparatus, comprising a best Spanish mahogany quarter-plate camera, first-class portrait lens, tripod stand, and all necessary chemicals and apparatus, for a bicycle forty-eight or fifty inches; also negatives of Indian scenery, seventeen splendid 10 × 8 plates, in strong plate box, for anything useful.—Address, B. Bentley, 21, Chatterton-road, Highbury, N.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

Photographs Registered.—

James Hargreaves, Union-street, Dalton-in-Furness.—*Two Photographs of His Grace the late Duke of Buccleuch.*

W. G.—Evidently you are employing a gelatine that is not suitable. Try a different sample.

Ignoramus.—Either paper will answer quite well for such small sizes as you name. For larger sizes perhaps that known as "thick Saxe" will prove more convenient.

A. N.—The machine is a copy of Eastman's, which has previously been described in our columns. Copies of Mr. Eastman's specification may be obtained at the Patent Office.

Wm. Otway.—The idea is by no means novel. A series of similar pictures were published many years ago; but, if we remember rightly, they met with but little commercial success.

Viotti Krommer.—The water must be very peculiar to act as you describe. We never heard of such a complaint before. Why not employ rain water on every occasion, and thus avoid all difficulty?

S. J. Winn.—1. Yes.—2. Doubtless no fraud was intended. It was clearly an error. Write to the firm, and they will certainly rectify it.—3. The fault of the varnish, as you surmise.—4. Not that we are aware of.

R. A.—Kindly repeat your query and we shall be pleased to assist you. As you did not enclose name and address your previous communication, according to our usual custom, was consigned to the waste-paper basket.

R. Arnold.—For the early history of photography you cannot do better than procure a copy of Hunt's *Photography*. It has been out of print for many years, but copies may often be met with on second-hand bookstalls.

M. A. (Cambs.).—Opinions differ very much as to which is the better—dark slide, or a changing-box. Some photographers use both—the changing-box when they take a large number of plates into the field, and dark slides if they only take half-a-dozen or fewer. If you only require to take three or four plates out, with a changing-box your equipment is as cumbersome as if you took a dozen.

Eugene.—There is no objection to your having plants in the studio, provided they are so placed that they do not interfere with the lighting of the sitters. The perfume from them will certainly have no injurious action on the plates.

G. P. C.—Twenty to thirty grains of gum dammar dissolved in each ounce of benzole will make a good transparent varnish which will dry without heat. It will do very well for glass positives, but is hardly durable enough for negatives.

Somerset.—It is doubtful if the photographer be entitled to use the royal arms unless he has some further right than that you mention. We fancy if you were to employ them you would incur a penalty of twenty pounds. So far as we can judge from so small a picture, the lens appears to be a fairly good one.

B. B. Benton.—From what you say we imagine there is no fault with the japan itself, but that you have failed to use it properly for your tin developing dishes. You appear to have omitted an importont operation, namely, "stoving;" that is, keeping the work hot in a japanner's oven for some length after the japan was applied. Hence the cause of failure.

J. Acres.—The lens is a decided "swindle." The mount is nicely got up, but the glasses are simply plain lenses—spectacle eyes, in fact. The lens is quite worthless for photographic purposes. Doubtless, if you apply at the address given, and where you sent the remittance, you will find the vendor is unknown. We return the lens per parcels post, as requested.

Inquirer.—The cause of your failure is, doubtless, due to having too little body in the picture. The transparency should be very intense before it is toned, and the toning should be very complete. Possibly, as you send the enamels to a china works to be burnt-in, they have been over-fired. Much less heat is required for enamels than for china. No glaze is necessary, but you must use soft enamels.

J. T. Houlden.—The fogging which "always occurs in the same part of the plate" is due to light in the camera—possibly reflected from some portion of the lens mount. Take the camera into a strong light and focus the image. Then remove the ground glass (keeping the head covered with the focussing-cloth) and carefully examine the interior of the camera and lens. In all probability the source of the evil will be at once discovered.

E. G.—A dark green baize of fine texture will answer the purpose very well, and is not likely to fade if the fabric be of good quality. Take care that the colour is not a bright one, for two reasons: a very brilliant colour will detract from the pictures; and very bright colours, as a rule, are more liable to fade by the action of light than those which are less brilliant. Our correspondent, at the conclusion of his communication, says:—"I have found a saturated solution of sulphate of iron and a saturated solution of citric acid—say one ounce of iron solution and a few drops of citric solution added—a capital thing to reduce over-density in gelatine negatives. If the negative be too dense when taken out of the fixing-bath I put it into the above solution without washing, and the density is soon reduced."

Received.—A. Conan Doyle; W. H. Harrison; C. G.; *Picture-Making by Photography*, by H. P. Robinson.

ON THE DEATH OF THE REV. F. F. STATHAM, M.A., LATE PRESIDENT OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

Only removed, transplanted to a higher sphere
And more congenial climes, he lives triumphant there.
The flickering lamp too early brought the gloom of night;
But, trimmed afresh, it sheds a more refulgent light.
We mourn his loss, affections strengthened year by year,
And vain the effort to suppress the rising tear.
His smiles were like the genial warmth of early spring;
No evil thought himself—sanctioned no evil thing.
Strained eulogy is needed not his worth to prove—
His every act was kind and fraught with Christian love.
Keen sympathies, refined, through his whole nature ran;
Say what a man should be—he was in truth that man.

William Cobb, Woolwich.

Photographic Club.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 7th inst., the subject for discussion will be—*On the Colour of Negatives as Affecting the Positive Prints.*

Photographic Bankruptcy.—The first meeting of the creditors of Robert Banks, photographer, who carried on business in Manchester and Blackpool, was held in Manchester on Tuesday last, before the official receiver, Mr. C. J. Ditt. Owing to a technicality in the new Bankruptcy Act only four of the creditors had legally conformed with the rules. It was stated that two of the bankrupt's houses were morgaged for £1,179, and it was believed that, if the property were sold, no more than this sum would be realised by the sale. There was also a sum of £220 deposited for photographs which were not supplied, but, in the opinion of the receiver, it was not probable that much trouble would be caused by these small creditors. The net deficiency of the bankrupt was £289 9s. 5d., and this sum could be realised by a sale of the business effects. A trustee and committee of inspection having been appointed, the meeting terminated.

IODIDE OF SILVER IN EMULSION.

Mr. W. K. Burton's article in our last number, on *The Mixing of Emulsions of Different Sensitiveness*, suggested one or two points for consideration in connection with the use of iodide of silver in gelatine emulsion. Iodide of silver is commonly supposed to be unacted upon by the alkaline developer, and, therefore, its function in emulsion is held to be a purely mechanical one. The first part of this proposition has, however, been proved to be a fallacy, as iodide of silver has been found to be reducible by a powerfully-alkaline pyro. solution, though it is practically unacted upon by the developer of the ordinary strength employed for bromide of silver. Such being the case, it would seem that in an ordinary emulsion film containing both bromide and iodide of silver, the latter, being beyond the reach of the normal developer, would play a purely mechanical part in giving density to the film, and, by isolating the particles of bromide, preventing halation, as pointed out by Captain Abney.

This would appear to be the case if we accept it as a fact that under these conditions the iodide does really remain unreduced. But is it so? Some three or four years ago, during the period when the question of iodide in emulsions was undergoing discussion, we found that in an emulsion containing iodide made in the usual manner by mixing the soluble haloids with the gelatine before sensitising, the small trace of iodide employed did suffer reduction under the ordinary developer. This we attributed to the possible formation of a compound—a bromo-iodide of silver—in which the iodide became more susceptible of reduction. From the difference in the behaviour as regards sensitiveness and other properties of a bromo-iodide emulsion, made by mixing separately prepared bromide and iodide, we judged that this combination did not occur under such circumstances, though we gave no special attention to the matter at that time.

Mr. Burton's paper and our remarks thereon in our last number, however, brought the subject back with renewed interest, inasmuch as it seemed more than probable that the same action which causes the reduction of unexposed particles of bromide when in contact with exposed particles might also secure the reduction by an ordinary developer of silver iodide when in contact with exposed bromide.

In order to test the question a bromo-iodide emulsion was prepared containing iodide in far larger proportion than is customary. The bromide and iodide of silver were emulsified separately, each emulsion containing twenty grains of silver nitrate to the ounce, converted respectively into bromide and iodide. These were mixed in equal proportions. No account was taken of the sensitiveness of the mixture, as our only object was to discover whether and under what conditions the iodide of silver contributed to the formation of the developed image. Plates were coated with the mixed emulsion and also with each of the separate ones, so that we had plain bromide, bromo-iodide, and plain iodide films for comparison.

The first experiments, made by exposing the plates in the camera, were fruitless, owing to the wide difference in the sensitiveness of the three films. The plain iodide, in fact, refused, as we anticipated, to give any image at all; while it was impossible to tell how much of the difference between the remaining two was due to difference of exposure, and how much to difference of constitution. In fact, we found it necessary to relinquish the attempt at comparison in this manner.

Next, a bromo-iodide film was exposed behind a cardboard mask for a few seconds to weak diffused light, then developed unti apparently no further reduction would take place, and the image of the opening on the mask was clearly visible at the back of the plate. One half of the film was immersed in the hypo. bath until thoroughly fixed, when an examination of the fixed and unfixed portions of the developed image showed that the latter was decidedly the denser of the two.

This experiment proved of little real value; for it assumed as its starting-point that the whole of the reducible haloid, both bromide and iodide, had suffered reduction under the combined action of light and development. This assumption is by no means proved, and the loss of density in the fixed portion of the image was as likely to be due to the removal of some unreduced *bromide* as to unreduced iodide.

Another plate was exposed and developed in the same manner, and after thorough washing and "aluming" one half was cautiously treated with dilute nitric acid, without fixing. This slowly removed the reduced silver forming the image, but leaving a considerable amount of opalescence, which might consist of iodide or bromide or both. Treated with dilute ammonia the residue proved to consist of both iodide and bromide, but the results were so far incomplete and inconclusive.

The last experiment, however, left no doubt. A plate was exposed, developed, washed, and "alumed" as before. One end of the plate was then immersed to one-third of its length in dilute nitric acid until the developed image was removed. After again washing the opposite end of the plate was immersed in dilute ammonia to remove the unreduced silver bromide. We had now a plate showing three bands, the centre of which represented the original film before exposure as well as the image after development. One end represents the original film in juxtaposition with the residue of unreduced silver haloid left by the nitric acid; while the third portion represents the original film and the developed image with the whole of the bromide removed. A single glance suffices to show that the iodide of silver has been almost entirely reduced; for, on comparing the unexposed portion of the ammonia-treated end with the exposed portion of the acid-treated end of the plate, the former is found to be many times denser. In other words, the residue of exposed and unreduced haloids (both iodide and bromide) is far less opalescent than the residue of unexposed iodide. A drop of ammonia placed in the centre of that portion of the image from which the silver has been dissolved shows that a portion of the residue is bromide of silver, and that, therefore, the maximum action of light and development has not been attained. If such maximum can be attained it seems reasonable to suppose, therefore, that, in the presence of exposed silver bromide, silver iodide suffers total reduction under a developer of ordinary strength.

The establishment of the fact that silver iodide is not, as many suppose, so much inert matter in emulsion has an important bearing on the question of the sensitiveness of bromo-iodide emulsion. Many still cling pertinaciously to the idea that iodide necessarily slows an emulsion, and that the acme of sensitiveness is unattainable in the presence of iodide. Our own opinion, long since expressed, is quite the reverse; and it is corroborated by the fact that some of the most rapid commercial plates in the market, as well as some of the most rapid of private manufacture ever made, contain iodide.

SULPHITE OF SODA AS A DEVELOPER.

A fortnight ago we brought before our readers an account of a number of experiments we had been making with the above salt, showing that in combination with pyro. it aided development so as to be capable of entirely taking the place of ammonia. We also explained that when added to a carbonate of soda developer it greatly heightened the sluggish action of the latter; and, further, that in none of the trials we made did the sulphite either act as a restrainer or cause the negatives to exhibit a trace of green fog, the last two accusations having been freely made against it at one time or another.

We have since then made a very large number of experiments with sulphite as a developer, which in every way confirm our previous results, and shed, at the same time, much new light of an interesting nature upon the action of that salt. The experiments we last detailed were with comparatively weak solutions of the sulphite, four grains being made to take the place of one minim of strong ammonia solution. The time required for development being an hour and a-half, it was evident that, to obtain a practical success, this must be considerably reduced. We, therefore, tried gradually increasing quantities of sulphite, till at last we employed a solution almost approaching saturation. Not to detail every step of our investigation we may say that with such a solution (twenty-five per cent., to speak accurately) we were able to take a satisfactory negative with from fifteen to twenty minutes' development.

Having arrived at this stage, the next step was to make comparative trials with ordinary ammonia and bromide pyro. developers, so as to obtain the ratio of speed and other data.

Developing two plates which had received identical exposures side by side, we found that the ordinary developer gave an image apparently about ten per cent. more exposed than the sulphite developer. We then tried the effect of a restrainer, and this made a very great difference in the effect. So small a quantity as one grain of bromide of potassium to nine grains of pyro. "slowed" the plate to a very large extent, necessitating an exposure three or four times as great as when not used. A quarter of a grain to the same quantity of pyro. reduced this slowing effect to a more workable degree, and gave a negative of first-rate quality, though with increased exposure still being necessitated.

So far we had thus extracted the best value out of the new developer that could be obtained without any aid from other developing agents, and our next step was to see what the effect would be with the addition of ammonia in various proportions to the sulphite developer, our previously detailed experiments showing the result gained with carbonate of soda. We gave identical exposures to two plates, and to ensure the trustworthiness of our results in this series we developed these trial solutions side by side with the developer with whose action we were quite familiar. (To avoid repetition we may state that all the experiments were made with the pyro. of a strength of two grains to the ounce; and when we speak of a pair of plates we refer to plates having received exactly similar exposures). The sulphite solution was of the same strength throughout, an ounce by measure contained a-quarter of an ounce of sulphite. The "ammonia-bromide" solution contained half as much bromide as ammonia. We will term it "normal" when the ammonia added was half the weight of the pyro. In making such experiments we prefer to stop down our lens, so as to lengthen the time sufficiently to enable us to make exposures that would not vary more than one or two per cent.

A pair of plates were developed — one with pyro. in solution of sulphite, the other with ammonia bromide in water, one-third normal strength. Here the sulphite developer was unmistakably the quicker, and to find the rates we gave increasing exposures to different sets of plates; but when the sulphite-developed plate received only half that given to the plate developed in the other solution it was apparently far more exposed. We did not see the utility of proceeding further with this stage of the trials; we should, however, estimate that with the foregoing solutions the sulphite developer would require only a fourth or fifth of the exposure needed for the weak ammonia bromide.

We then tried the effect of adding ammonia to the sulphite, and we found a distinct gain in rapidity for the mixed developer. A pair of plates were developed with normal ammonia bromide in water for one, and in sulphite solution for the other. There was a clear gain of about ten per cent. in favour of the sulphite. When the strength of the ammonia bromide was doubled, which was the proportion we found best for the particular plates we were employing, the gain was still equally perceptible.

At this point we leave the matter in our readers' hands. To sum up our results: they clearly show that sulphite of soda solution and pyro. with no additions, though capable of producing negatives of great excellence, possess no advantages over the ordinary pyro. developer, and are inferior to it as regards the time required to complete a negative; but that such development can be performed satisfactorily is a fact well worthy of being placed on record, as, *a priori*, it would not be considered probable.

Finally: the verdict as to the effect of sulphite of soda in the developer, apart from its developing properties, was foreshadowed by us a fortnight ago in the trials we made with carbonate of soda. The experiments we have completed have involved the expenditure of considerable time; but they emphatically show that sulphite of soda, so far from being a retarder of development, or even of the process of development, has the very opposite effect. It is an accelerator, it does not produce green fog, and, in case of emergency, is capable, when added to pyro. solution, of developing the image without help or addition.

INCONGRUITIES IN SCENIC BACKGROUNDS.

It was, doubtless, owing to the lateness of the hour that the subject of scenic backgrounds to portraits was not treated by Mr. Norman Macbeth during his instructive lecture at the meeting of the South London Photographic Society last week; and when, in the course of a brief discussion which followed, a member endeavoured to get the opinion of the able lecturer on this subject, by inquiring as to the principles by which artists are guided in determining the position of the horizon line in the scenic background of a portrait, there were probably other things which may have prevented the scope of the query being observed.

But the misapprehension as to the question elicited from Mr. Macbeth one piece of information of interest, namely, that in painting a figure the artist adopts a shifting point of sight—one which shall always be immediately in front of the particular portion of the figure which he is at the time painting or drawing. For example: when painting the boots or feet of the subject be would bring his canvas down opposite that portion of the figure, and gradually raise it as he proceeded upwards (or *vice versâ*, as the case may be), until when the head was reached—if the subject were a tall, standing figure and the painter deficient, as some painters are, in longitudinal proportions—the artist would have to mount a platform or obtain the elevation afforded by a pair of steps, in order to complete his drawing under uniform circumstances.

Photographers, however, cannot resort to this method of securing parallelism, and it would be carrying conventionalism too far did they attempt to do so. The only thing left for them is to strike a line somewhere between the offensiveness of the realism resulting from an abrupt perspective caused by having the point of sight too near the subject, and the practical impossibility of a point of sight placed at infinity so as to secure parallelism of lines. Such a compromise is possible by placing the standing figure at a distance of not under thirty feet from the camera; and, if adopted, it would prevent young ladies from denouncing photographers for having represented them with feet of monstrous dimensions when the peculiarities of the pose necessitate the feet being visible.

This adoption of different points of sight in one picture explains what some photographers have designated the unreality and impossibility of one of Raffaelle's cartoons, *The Transfiguration*, which is intended to illustrate scenes that are transpiring simultaneously at the top of a "high" mountain and at its base. The whole of the details of the scene at the base indicate the point of sight as being very close to the actors grouped in the scene; and, from such point of sight, although it is quite possible the mountain top might also have been seen, yet it is barely probable. Hence for the transfiguration scene itself the point of sight has been raised to nearly the mountain summit; and, not only so, but it is brought much nearer to the figures there depicted. But photography, being a realistic art, must eschew the conventional tricks of the painter, and this brings us back to the scenic background.

It was stated by a speaker, at the termination of Mr. Macbeth's lecture, that several photographers who had justly the reputation of being eminent in their profession, especially as regards the lighting and posing of the figure or figures forming a picture, possessed so little knowledge of perspective, and those laws which determined the adjustment of a scenic background to the figure, that the horizon in such ground, which should in most cases be on a level with the head of a sitter, was in many instances so ignorantly or recklessly placed as to be no higher than the hips or even the knees, implying that the camera was brought down to that level when taking the portrait.

Now, as in nature the horizon in a landscape is opposite to the eyes, or point of sight, so should it be in the photographer's studio, in which the horizontal line of the scenic background ought to be placed as nearly as practicable on the same level with the lens. This would render impossible the perpetration of incongruities of the nature hinted at; and, although slight departures were made from this rule, still there would be nothing in the resulting picture to greatly shock the sensibilities of an educated observer. Even a superficial knowledge of perspective and its applications would be much better than none at all.

A scenic background should never have a horizon line of a pronounced character, and when such indefiniteness happily prevails it may, without interfering with the head of the portrait, be brought up to its level; and whereas we are most familiar with the faces of our friends when viewed from a point approximately of the same height, so ought the photograph, in order to be a good and easily-recognised likeness, also be taken from that altitude, whence it follows that the horizon line of the scenic background will also be on the line of the head, assuming such a background to have been employed.

But truth in nature is not apparently greatly outraged if we take a slight liberty with realism, and lower the background six or eight inches from the point dictated by strict accuracy. This slight degree of pandering to conventionalism does no harm, while it may be the means of withdrawing from the immediate surrounding of the head a horizontal line which would be a serious interference. While no background painter possessing proper skill would allow a well-determined line to cross the scene in the vicinity of the head, yet, unfortunately, such do exist.

We are not here contending for the display of taste in backgrounds, otherwise we would say that the scene should be only faintly suggestive instead of being depicted with full, pronounced detail; but we do contend that photographers themselves should make an aim at being at least approximatively accurate in the selection and placing of the background, so as to avoid the incongruity of seeing in the photograph two entirely distinct perspectives. Go to nature for a few minutes, and when you and your friend are walking in a field stop for a moment and examine the relation between the horizon and the friend, when the former will be found on a level with the head of the latter.

A USEFUL APPLICATION OF THE BITUMEN PROCESS.

The practical hint about to be given is one that may prove of value to professional photographers for producing, by very simple means, a copper plate from which the design or imprint on their mounts may be obtained. Many photographers are capable of making a tasteful and original design for the back of their mounts, but find when they come to have it engraved of several different sizes, it becomes a somewhat expensive matter, particularly if the design be of an elaborate description; hence they frequently have to be content with the stock, and sometimes hackneyed, patterns of the mount manufacturers. If the design be simply written direct upon the stone the cost would certainly be less, but the result is never so good as when transferred from an engraved copper plate.

By the method about to be described any photographer of ordinary intelligence may produce his own printing plates—either for his mounts, billheads, or address cards, and without any previous knowledge whatever of engraving — at a cost (however elaborate the design may be) but little exceeding that of the copper plates themselves. The process is simply a photo-etching one.

In the first place, the design and lettering must be drawn or written on a sheet of smooth cardboard, and from this a negative is made. The best plan is to make the design on a larger scale than is required for the plate—say on a royal or imperial board. The advantage in proceeding in this way is twofold:—First, the drawing need not be quite so neatly done, for when it is reduced any trifling defects will be less noticeable than if it were made the same size as required for the plate. Second, when the design is on a larger scale it may be reduced in copying to any size that may afterwards be required, so that one drawing will suffice for several different sizes. From the large design a negative is now made. This should be fully exposed, so that considerable vigour may be obtained in the development without risk of clogging up the finer details, which would be the case if it were at all under-exposed. The negative may be produced by any process; but it is essential that the lines be clear, transparent, and as free from fog and veiling as possible.

Now, if we were to employ our negative direct for producing the etched plate, we should get just the reverse of what is required. Therefore, from the negative we must take a transparency. This must be very strong, the lines being as black as they can well be made, while the other portions are as free as possible from veiling. This quality it is impossible to obtain unless the negative, in the first instance, be tolerably strong. If the transparency be made by camera printing the negative may be taken somewhat larger than the largest size plate required; then from it any number of smaller sizes may be obtained at will. Thus one negative will serve for any size of transparency.

A suitable transparency having been obtained, the next thing is to produce from it the copper printing plate. Copper plates of different sizes may be obtained from any establishment which supplies printers' materials. Possibly, however, if the plate have been long in stock its surface may be somewhat tarnished. In that case it must be repolished with wash leather and a little precipitated chalk moistened with methylated spirit or benzole. In all cases it is a good plan to subject the plate to this treatment, so as to ensure its freedom from all traces of greasy matter left in the polishing. The plate is now attached to a pneumatic plate-holder, and a dilute solution of bitumen in benzole is poured on and drained off in the same manner as collodion and dried. With regard to the strength of the solution little can be said, as different samples of bitumen vary considerably in their characteristics; but, as a rough guide, we may mention that it should be of such a strength that, when dried on the copper, it should only be sufficient to communicate a slightly-brown tint to the metal.

The transparency (which should previously be rubbed over with a little French chalk as a safeguard against the bitumen adhering to it while printing) is placed in a pressure-frame with the bitumenised plate upon it, and then exposed to light. Strong sunlight is the best; three or four hours will generally be required. In diffused daylight as much as two or three days may be necessary, as the bitumen process is an exceedingly slow one. When the print is deemed to be sufficiently deep the plate is removed from the frame and placed in a dish of turpentine, to dissolve the bitumen where the opaque portions of the transparency has protected it from the action of light, leaving the copper bare. With some samples of bitumen, however, turpentine alone will not dissolve it; hence, if it be found after the lapse of a few minutes, that the bitumen is not being dissolved, a little benzole must be added, bearing in mind that too much of this will dissolve the whole of the film, even where the light has acted. When the copper has been rendered bare in the lines the plate is rinsed in clear turpentine and then dried.

The plate should now be carefully examined, and if the design show any imperfections it should be cleaned off with benzole and a new one produced. Full and complete working details of the bitumen process, which is given here only in outline, will be found on pp. 595 and 607 of our volume for 1882, to which the reader will do well to refer before commencing operations.

The photographic portion of the work being completed, the back and all those parts of the plate—except, of course, the lines—which are not protected with the bitumen are painted over with Brunswick black. The plate is then immersed in a dish of the etching fluid. The one we prefer is a strong solution of the perchloride of iron; but professional etchers, as a rule, use dilute nitric acid—one part of acid to two of water—the bubbles of gas, when this agent is employed, being removed by gently rubbing the surface of the plate over with a feather. When it is judged that the design is bitten in sufficiently deep the plate is washed and dried and then closely examined. If the lines are not considered deep enough the plate is replaced in the fluid, and the etching continued. If there be much very fine detail in the design it is sometimes advisable, before re-immersing the plate, to paint such portions (where it occurs) over with Brunswick black, so as to protect them from further action, as it is not desirable that the finer lines should be so deep as the bolder ones.

When sufficient depth is attained the plate must be thoroughly washed with water to remove all traces of the etching agent. Finally, the bitumen is cleaned off with benzole, and the plate is then ready either for printing from direct, or for producing impressions to be transferred to stone and afterwards printed from lithographically.

It is not often that the photographer is likely to injure himself by accidentally splashing nitric acid upon his skin, though when collodion was more used than it is at present this was by no means infrequent. Still, the acid is employed, and a method of preventing any ill effect from such an accident will be useful to know. A writer in the *Chemical News* states that he recently met with such a disaster, the acid going on to his face. Copious effusion with cold water, followed by the application of ammonia, potash, lime in water, &c., were tried, and without effect. Considering the action of the acid to be an intensified process of oxidation, he applied a weak solution of sulphurous acid, so that the nitric acid might spend its energy upon oxidising it. The result was marvellous. The blisters were reduced in a few minutes, the irritation removed, and in an incredibly short space of time the wound healed.

We have been making a calculation as to the amount of metal required for the aggregate amount of type that has been employed during the last twenty years to "set up" in various periodicals announcements of the discovery of photographing in colours. Three lions from Trafalgar-square and a griffin could be cast from them, and still leave some to spare. The turn for the repetition of the perennial story has come round again, so *The Times* informed us last week that "an engineer at Versailles claims to have discovered the art of taking photographs in colours; or, in other words, of reproducing the colours of the body or landscape photographed."

The Bodleian Library, among its treasures, holds the Hope collection of engraved portraits, numbering some two hundred and ten thousand, and it is taking steps to increase the number largely. The librarian has issued a notice asking for the presentation of interesting objects, which he classifies under four headings, the last being directed to authors, inviting them to present the library with their photographs and engraved portraits, and to add on the back their full names and any other particulars. By "authors" the librarian understands composers of printed books, pamphlets, magazine articles, maps, and music, his design being to form and perpetuate a portrait gallery of literature.

In these days, when almost every other man is, or claims to be, an "author," the mass of portraits which would accumulate if the appeal were fully responded to is appalling to think of; hence the recommendation we had almost penned may be left unwritten. It was to the effect that the librarian should add to his notice the word "permanent" before photographs.

By-the-way, the engravers are making use of one of poor Rejlander's pictures—the new edition of Lord Tennyson's works, to be published the first of next month, being illustrated by a portrait engraved by Mr. G. J. Stoddart from a photograph taken by the late Mr. O. G. Rejlander.

Are we to have a new Copyright Bill at last or not? Mr. Hastings introduced one again last week, and on Wednesday it passed the the first reading in the House of Commons. We have not yet received a printed copy, but we understand that in its main features it resembles that introduced last session.

Last year's Bill has, however, been carefully revised, and the celebrated suit of the Stereoscopic Company—in which, as our readers may remember, the Company lost its case through a successful contention being raised that the "author" of the registered picture was not Mr. Nottage—has been the cause of certain modifications and additions being made, in order to prevent future disputes as to "who is the author of a photograph." Mr. McLaren introduced a short Bill last session to meet this point, but it was dropped at an early stage.

Most of our readers have heard of the Jablochkoff candle—one of the earliest departures of a novel character in modern electric light. The inventor, from whom it derives its name, has recently devised a remarkable kind of battery in which metallic sodium in thin plates takes the place of zinc or other similar element. When not in use the sodium is covered with a hydrocarbon to prevent oxidation. A company has been formed in Paris to work this sodium battery, which is stated to possess by far the highest electro-motive force of any battery known.

We have often alluded to the useful department for the examination and verification of scientific instruments at Kew—an establishment whose scope of usefulness is still unknown to a large majority; though, when it is borne in mind that for a trifling fee a thermometer, for example, can be examined and its performance given to fractions of a degree upon every degree of its scale, the wonder is that it is not taken advantage of to a far greater extent. Though a photographer in some delicate operations should always be provided with a thermometric instrument to be depended upon, it is rare that he is called upon to undertake operations where the utmost exactitude in time-keeping is required. It may, however, be interesting to learn that he can now send even his watch to Kew, and for a sum varying from five shillings and sixpence to one pound, according to the class desired, have his watch examined and a certificate of its rate given to him.

The Liverpool Astronomical Society—the only similar Society out of London—has done good work in photography, as our pages have shown. Our learned contributor, the Rev. S. J. Perry, F.R.S., whose article on astronomical photography at Stoneyhurst Observatory, which we gave to our readers a few months ago, was found of such great interest, has testified to the same fact. In a lecture he recently gave before the Liverpool Astronomical Society upon *Sun Spots*, he recommended attention being given to a branch of the science but little pursued—the photographing of "faculæ and rice grains," as certain peculiar appearances upon the face of the sun are termed. By that means, he said, it was very probable the nature of sun spots might be discovered. If the Society attempted it and succeeded as well as they had done in some of the stellar photographs he had seen, he "would venture to say their sun pictures would be second to none in the world."

We do not often hear of the magnesium light nowadays, except in connection with sensitometer experiments. Its comparatively high price has made its use a luxury, or even a curiosity, rather than a necessity. And now that the electric light has made such progress it is doubtful whether magnesium, even if provided at a much lower rate, would take a leading place in photographic operations. But experimenters are still at work, and often have we been promised marvellous reductions in the price of the metal, which is mainly governed by that of sodium—the chief factor in its economic production. A process for the production of magnesium by electrolytic agency has been patented, and, as a test of its capability, Dr. Fröhlich lately brought before the Berlin Academy of Sciences a large lump of metal made under the patent. The mode of manipulation is to fuse chloride of magnesium, and to decompose it by the electric current while in a state of fusion.

PHOTOGRAPHY AT A FANCY DRESS BALL.

One of the latest novelties in connection with the practice of photography, and one which a few years ago would have been regarded as an imaginative dip into Utopia, is the system which has prevailed during recent years of photographing the guests at balls during the course of the proceedings, thus saving the trouble involved in the necessity for specially dressing for a visit to the photographer. The introduction of artificial light into the photographer's studio in a measure did away with the need for a special "dress rehearsal," as the person was thus enabled to call at the photographic studio on his or her way to the ball itself, and, at the expense of a few minutes' delay, secure the desired picture. Even this slight amount of trouble deterred many from securing such representations of themselves in costumes removed from those of everyday use, the opportunities for which, especially in the case of fancy dress and masked balls, are of sufficiently rare occurrence to render them noteworthy incidents in social life.

It remained for the late Signor Lombardi to solve the difficult problem of how to induce the ball-going public to become ready and remunerative clients of the photographer. His happy conception of taking the studio to the sitter, instead of trying to entice the sitter to the studio, was from the first a success both photographically and, we should say, financially. By means of the luxograph apparatus—which, by its simplicity, does away with the costly and cumbrous appliances required for the electric light—Signor Lombardi, assisted by Mr. Alder, the patentee of the luxograph, some five years ago made the first successful experiment in establishing a photographic studio, if not in the ball-room, at least in an adjoining apartment or ante-room. The measure of success may be calculated when it is stated that something like a hundred and fifty negatives were taken on that occasion. The electric light has since been used in a similar manner in Paris on the occasion of a *fête*, and subsequently in London the famous Cromwell House "*posés plastiques*," and the recent fancy ball of the Savage Club in the Albert Hall, have been so treated. But it is only the simplicity and portability of their apparatus which enables the Luxograph Company to make a special feature of this class of business.

Curious to see what progress they had made in the course of five years in the establishment of a smoothly-working system, we seized the opportunity of dropping into the "photographic room" during the progress of a private fancy-dress ball at one of the large West End halls, having previously called to inquire whether photography was to form part of the evening's programme. At 5 p.m. we found Mr. Alder superintending the commencement of the erection of the needful apparatus.

This consists, as many of our readers are aware, of an immense reflector lined with silvered glass, by which the light is thrown upon the sitter. This, with its pedestal, stands some eight or ten feet high, so that it is not the most comfortable of pieces of apparatus to move about. In the centre of the back of this reflector is a large lantern glazed with blue or violet glass, in which the compound that produces the light is burned. The products of combustion are of a most poisonous and suffocating character, and must, therefore, be led away into the open air. This is easily effected by means of a few lengths of sheet-iron stove pipe passing from the lantern to the upper part of one of the windows opened just sufficiently to allow the tube to pass out into the open air. In wet or windy weather the open window is protected by nailing over it a thick cloth or canvas.

So perfect is the system that less than an hour suffices, in a strange place, to erect the apparatus and make all the needful arrangements; and during the whole of the "subsequent proceedings" the clients remain in happy ignorance of the fact that they are only divided by a thin screen from the highly-poisonous and almost unbreathable smoke produced by the combustion of the pyrotechnic compound. The apparatus itself travels comfortably by rail, the particular one whose erection we have witnessed having traversed a good many miles of country in its time. As we leave to prepare for the evening, Mr. Alder informs us "it will only be a small ball; one hundred and eighty are down for supper, and that is about the number of sitters we reckon to secure on big occasions."

Later on, about ten o'clock, we leave the brilliantly-lighted ball-room, with its bright colours and ever-changing forms, and find our way to the quieter and less brilliantly-lighted apartment devoted to photography. We are warned as we enter, by the soft blue light that fitfully illuminates the centre of the room, which is hidden from us by the background, that an exposure is being made. We wait until it dies out, when from behind the background emerges a fairy form gorgeous in white satin and hair powder, and representing—goodness only knows what! She is followed in rapid succession by three or four cavaliers in court costumes of much similarity in style but diversity of detail. Then follow a heterogeneous collection of characters of more or less (some principally the latter) gorgeousness—from the bejewelled Indian prince, the Spanish *danseuse*, the coquettish *cantinière*, in her smart dress, tasselled boots, and (let us whisper it) immense "dress improver," to the typical barrister in wig, gown, and check pants, the gentleman in the canon's uniform (which somebody irreverently describes as that of a "Somerset House porter)," and, lowest of all, the young man who turns up in his last season's lawn tennis costume. We looked on as each took his or her turn, and could not help remarking how most of them entered into the spirit of their respective characters. The supercilious *nonchalance* of the courtier raised a desire to kick the individual who in everyday life was probably a stockjobber. The spanish *danseuse* appeared anxious to favour the small audience with a gratuitous performance on the tambourine during the exposure; while our *cantinière*, when persuaded that she would not be able to keep still long enough in the act of delivering a military salute, became content to devote her attention to the exhibition to the best advantage of her top-boots and dress improver.

The light for focussing was derived from a line of gas jets surmounting the reflector, the operation of capping the lens being unnecessary, as, except when the pyrotechnic mixture is burning, there is no light sufficiently powerful to affect the plate. The exposures are measured by the quantity of the burning compound, and seemed to average from twelve to fifteen seconds with a lens somewhat stopped down. By a division of labour the work proceeded smoothly and rapidly. One to arrange the subject, one to manage the light, a third to change the plates and take the names and addresses, formed the complete staff. The subject having been posed and focussed, a signal is given and the sound of a "vesuvian" striking is heard. This dropped into the dish of burning compound, the door of the lantern is closed and the exposure commences. No plates are developed on the spot, as, from a perfect acquaintance with the value of the light, errors in exposure are rare. "Have you many failures from any cause?" we asked. "We had one at our last ball," was the reply. "It is impossible to always to detect a move, but if we see unsteadiness or have reason to suspect actual movement we repeat the exposure; otherwise we trust to the first plate."

We learnt subsequently that at this "small" ball (there were about a couple of hundred dancers) between fifty and sixty cabinet pictures were taken, two only of which were spoilt by movement of the sitter. We concluded that, while this system is an undoubted convenience to the sitter for the reasons already stated, it may be made a most remunerative one to the photographer; and it is to us surprising that it has not become more popular than it is at present.

NOTES ON THE COMPOSITION OF A PICTURE.

By Norman Macbeth, R.S.A.

[An abstract of a communication to the South London Photographic Society.]

On entering on the subject which I have taken in hand, I wish it to be understood that a great portion of what I shall have to say will be of so desultory a nature that I expect more profit may be gained from the answers to questions put than from what I now bring before you.

Art is that power by which we manifest our individuality. Every man has his own way of treating a subject, and it is of great importance that he have a proper field in which to define his ideas; therefore the first thing under consideration in art is "the field of view"—that is to say, the space in which we are to exercise our minds.

Perhaps you have never asked yourself the question—"Why is it that pictures are oblong and not square?" We have the precedent of the square form in sculpture and in Roman architecture, but this is generally where the centre forms a special feature of design. In illustrations which are an evidence of expression and thought, however, the oblong, either vertical or horizontal, is always adopted. The reason of this is that we must have *variety* in all that we do by way of illustration. The difference between length and breadth affords this variety. As an example of the necessity for variety I show a square divided into four by two lines. A conspicuous object placed at the crossing of these lines is central; there is, therefore, no variety.

The best proportion between the length and breadth of a picture is got by taking the two sides of a square, the diagonal of which forms the length of the base. This proportion can be most beautifully filled. My own studio is built on these proportions, namely, thirty-five feet long and twenty-five feet broad. Having got the field of view, it is important to see how we should subdivide it to some purpose.

If we divide such a space equally into three portions—first vertically, then horizontally—we shall find that each intersection of a horizontal line with a vertical line gives a point where an object of interest may be placed. The same rule holds good if we divide into five, or with any odd number. But, if we divide with even, we land ourselves in the same difficulty mentioned in connection with the square: we lack variety. Attention should never be drawn towards the centre of a picture if possible, but rather away from the centre. Thus, if we are making the divisions into five parts, an object at one of the outer intersections will be more expressive than one more central. It is, further, to be noticed that if we choose as a point of interest on one side of our picture the intersections of any two certain lines we must not use the corresponding intersections on the opposite side, but another. It is easy to apply these principles to the camera by drawing lines on the ground glass, when the striking objects may be made to fall on the intersections of them. The principle which I have brought before you is very old. I first saw it in Howard's *Sketcher's Manual*, which I would strongly commend as the best book I know on the subject; but I fear it is now out of print.

In using the camera it is important to fix a good base line. This should be at least twelve paces from the point of view. There is a tendency with many photographers to bring the base line too near the camera by tilting the latter forward. Of course much in this matter depends upon the height of the camera. Thus, the view may be taken from the average height of a standing figure or of a sitting figure. If we take in portions of foreground too near us these appear too large in proportion to those in the distance. The base line may subtend an angle of 60° to the camera. More should not be included, as the eye cannot take in more without going beyond the sphere of its axis. As already explained, the centre of the picture should not be in the centre of the plate. To take, for example, a street view: it is a mistake to make the two sides of the street occupy equal parts of the plate. If the two sides of a picture are alike all interest ceases. It is necessary to distinguish between the "centre of the view" and the "vanishing point," the latter of which may be entirely out of the picture. [These matters were made very plain by the diagrams illustrating them.]

We now come to the question of the horizontal line of a picture. If we divide our field of view into three equal parts by two horizontal lines, either of these may be used as the horizontal line of our picture. It is a mistake to have the horizontal line in the centre, dividing the picture into two equal parts, as there is thereby a division of interest. Where the view is low, as in a sea view, the horizon line should be the lower of the two lines mentioned. When the view is high, as in mountain scenes, the upper line should be chosen. In the first case, room is left for the composition of clouds; in the second, for sufficient foreground, trees, and mountains.

In connection with sky composition, I need scarcely point out to you the benefits to be derived from double printing; but I would say a word in favour of the sky-shade for use when the clouds happen at the time to compose well with the landscape. I had the pleasure of bringing before the photographic world, some time ago, a sky-shade invented by Mr. J. Parker, of Glasgow. I find the best times of day for getting skies to be the afternoon and evening. Before I used the sky-shade I could not get the foreground sufficiently exposed at the same time as the sky, but now I can easily.

One of the charms of the works of the greatest artists is that the principles that I have enunciated can be clearly traced, and that they yet do not force themselves on one's view. The principles that I have given you are easy. The whole thing depends on the application; but, adhering to the principles, there is ample means for producing variety. It is true that these principles are by many artists not known. Still even many follow them as it were intuitively, being brought up with examples containing them.

In coming to speak of figure subjects, I should advise those of you who have not read it to get Burnett's book *On Composition*, which I can strongly recommend. He points out in what different forms a figure subject may be brought out—never square, but in a diamond, round, serpentine, or diagonal form.

When portraiture was first practised by photographers there was a tendency to place the head in the centre of the picture, leaving a great gap above or to the side. The following method will be found useful in deciding the position which the head should occupy:—For an "English head" let the distance between the top of the head and the top of the picture be a quarter-head length; for the "common head" size a half-head length; for the "kit-kat," where the hands are shown, three-quarters of a head length; for a "half-length" portrait a whole-head length.

Let me, in conclusion, commend to your notice Mr. H. P. Robinson's new book, in which there is much that is most excellent. I am only sorry that he has not shown more examples, less writing and more illustration, especially pointing out what to avoid, as well as what to pursue. [Mr. Macbeth very fully showed this by many diagrams which he had before his audience. He also exhibited a great many engravings taken from the works of the best painters during the last hundred years, most of which are to be found in South Kensington and the National Gallery. Mr. Macbeth strongly recommended all photographers to visit the exhibitions of the season, and make the composition of a picture their special study. Any novice can easily acquire the development of a plate, when he will find himself at sea in the management and direction of the camera.]

RAPID *VERSUS* SLOW DEVELOPMENT.

[A communication to the Bristol and West of England Amateur Photographic Association.]

The advocates of rapid development invariably object to slow development—first, on account of the extra time required; and, secondly, on the ground that developing slowly causes a discolouration of the gelatine film. Now, as to the little extra time required: this surely should be no objection to the amateur, who works for the love of the art. A few minutes more or less spent on each picture certainly should form no objection. I readily admit that a very protracted development may cause slight discolouration, but cannot consider this as any serious drawback, because such discolouration may readily be removed by a short immersion in the alum and citric acid solution; moreover, the advantages of developing slowly are so great that they would far outweigh the disadvantage of a slight staining of the film, even supposing such stain to be permanent and not removable.

A slow development undoubtedly gives a greater range of gradation between the high lights and deepest shadows, and as we have in nature an infinite number of gradations, it follows that a slow development will give a better and truer rendering of a subject than a rapid one.

In order to develope slowly, three courses are open to us: we may use a large proportion of bromide or a small proportion of ammonia, or may add the ammonia gradually, adding it by successive small doses until the desired amount of density and detail are obtained. This latter is the method I invariably adopt, and consider it gives by far the most satisfactory results, as it enables us to have entire control over the development, to avoid fog, obtain brilliancy combined with delicacy and softness, and, most important of all, enables us to correct errors of exposure.

In the instructions issued by most manufacturers of gelatine plates we are told to add certain quantities of pyro., bromide, and ammonia; then, if the picture flash out and show signs of over-exposure, we are directed to apply more bromide, or, in other words, when the picture is half spoilt, we are to do what we can to prevent its total loss.

I cannot help thinking that this method of proceeding is totally wrong, as it is building up a picture on an imperfect foundation; for, when once a trace of fog has made its appearance, it is impossible to successfully carry the development further without adding to the fog to a greater or less extent. But by slow development, even if a plate have been exposed five times longer than necessary, it is possible to produce a negative without the slightest trace of fog, and, moreover, without any loss of brilliancy—in, fact, equal in every respect to one which has received only the normal exposure.

Now, as an ounce of practice is worth a pound of theory, I propose to expose three plates under a transparency, to one of which I will give five seconds' exposure, to the second fifty seconds', and to the third one hundred seconds', or ten and twenty times the correct exposure.

I can admit that the professional photographer, working in the study with the light under control, may so accurately time his exposures that there may be no necessity for such careful and cautious development; but with amateurs who, like myself, practise upon all classes of subjects and under all conditions of light, errors of exposure must occur. Still, if we observe the rule of always giving a full exposure and developing slowly, not a single plate should be lost.

In addition to the absolute certainty of thus working, the results obtained are certainly superior to those by rapid development, having the pluck and brilliancy characteristic of a good wet plate.

Next as to formula for developer. I usually keep two stock solutions:—

No. 1.

Pyrogallic acid	1	ounce.
Bromide of ammonium	½	„
Citric acid	80	grains.
Water	8	ounces.

No. 2.

Ammonia	1	ounce.
Water	7	ounces.

To develope a half-plate: take four ounces of water, to which is added one drachm of No. 1; immerse the plate in this solution, and allow it to soak for a moment or two. Next measure out one drachm of the No. 2 solution, one-fourth or a-quarter drachm of which is poured into a measure and mixed with the pyro. solution in which the plate has been soaking. This solution is again poured upon the plate, and if sufficiently exposed the higher lights will slowly appear, but without much density. A second quarter drachm of ammonia is now added as before. With this addition the more brilliant half-tones will make their appearance, and the higher lights gain a little additional density. The third quarter drachm of ammonia is then added, when the details and faint half-tones will gain in force. The remaining portion of ammonia being added, the faintest half-tones will be brought out and the high lights have gained the full density, the resulting picture being, as far as development is concerned, all that could be desired. In the event of considerable over-exposure, the first or second addition of ammonia may be sufficient to fully develope the picture and give full density—in which case, of course, no further addition should be made.

I do not attach any importance to the formula I have given; any good standard formula may be used. The one great point of importance, however, is to commence with a small portion of the ammonia, adding it by successive small doses until the desired result is obtained. E. Brightman.

TRANSATLANTIC JOTTINGS.

The great interest with which the recent discussions on dark-room illumination have been followed in this country has been echoed in America, and society after society has taken up the question and discussed it in all its bearings. The Photographic Section of the American Institute, the Association of Operative Photographers of New York, the Chicago Photographic Association, and the Amateur Photographic Club of the same city have all in turn had before them the question of the best and safest light to use in the dark room. Most of them object to, or decry the use of, ruby glass, and the advantages of a screen or screens of a green hue in combination with one of red have been well set forth, though no striking decision has been come to by any of them.

One of the best things of the month, however, in connection with societies is an account in the *Photographic Times* (New York) of "A New Photographic Society." The preliminary meeting was held in Chicago, and was composed of about forty professional photographers. The Chairman briefly explained the objects of the meeting, and, when one of the assembled photographers asked if they were to understand the object of the new society was to advance the price of photographs, he replied in the affirmative. One member explained and apologised for having done pictures for three dollars a dozen, and recommended that others besides those present should be called upon to join the movement. Everyone seems to have promised to further the objects of the society, and it was arranged that the public should be taken into their confidence, and a notification advertised in two leading papers to the effect that good cabinets cannot be done at three dollars a dozen, the said notification to be signed by as many photographers as possible. It is evident from the discussion that not only are cabinets made at the low price named, but that the public are still further enticed by the presentation of chromos., panels, &c.

We reserve for the last the mention of one of the most amusingly-impudent letters we have ever read. A Mr. Hartley, instead of attending the meeting, wrote a letter giving his views in regard to their present movement, as he was the cause, he stated, of their meeting together. He explained how *he* came to do cheap work—of course, because others did it first; and how he, therefore, "swore that I would compel every gallery in Chicago to reduce their prices, which I acknowledge I have done." He further writes:—"I now wish to state that you can do nothing to advance the price so long as I say it shall not be advanced. * * * You have not the courage and backbone to advance the price on your own responsibility. * * * So the best thing you can now do is to adjourn the meeting, go home, and give your patrons more panels!" The Chicago photographers are evidently going to have nice times.

Society matters still: there appears to be no amateur photographic society in New York, and, in consequence, it is intended to start one, a notice being given to the *Photographic Times* to the effect that a meeting was to take place towards the end of March.

Another instalment of a neatly-illustrated paper, by C. A. Needham, on *Picturesque Photography*, appears in the March number of the same journal, and contains much readable matter and sundry good illustrations. We confess, however, to a slight feeling of bewilderment at seeing the description of two sketches of a cross with foliage twined round it. In the first picture the cross stands upright, but in the second it is thrown down and partly buried in the ground. The upright cross is an example of "rigid symmetry," and the second—the fallen cross—the same design "beautified by destroying its rigid symmetry, but preserving its *equilibrium*." True enough, perhaps, in one sense of the word, but inaptly chosen as a verbal illustration.

There must be something in the American climate inimical to the working of carbon processes, for we have more than once had to chronicle failures where success might have been anticipated. The climate is dry and the temperature at times excessive—two conditions either of which might be advantageous alone, but when conjoined are calculated to place considerable difficulties in the way of the beginner. At a recent meeting of the Photographic Section of the American Institute a letter was read from a gentleman in Malone, New York, describing his troubles with transparencies by the carbon process. He had made beautiful pictures for both windows and lantern slides, but after a few months they began to crack, and now be has not one of them left of presentable appearance. Mr. Mason (Secretary) said his experience had been similar. It should be known by these experimenters that if the plates had been carefully coated with gelatine and chrome alum before squeegeeing the tissue on to them the transparencies should have been able to withstand a very considerable amount of rough usage without giving way in any form. We have seen transparencies so treated subjected to every variety of temperature and of moisture without showing the slightest tendency to crack or peel.

Mr. Falk, whose remarkable photograph of a stage scene was noticed by us some time ago—a photograph of stage setting and actors in the "Russian Honeymoon"—has a long note in *Anthony's Bulletin* respecting his priority in the first successful attempt to obtain a photograph of the stage of a theatre with the actors upon it, some doubt having been cast by an art journal upon his claim to be the first. Some misconception seems to have arisen, founded upon the sequence of sentences in an article in the *Mittheilungen* treating upon this interesting photograph. The editor of the latter journal, however, clearly shows that he did not in any way call in question Mr. Falk's being the first to achieve the feat.

American photographers have not much to learn from their British brethren; but when we read that, at a meeting of the Association of Operative Photographers of New York, Mr. Buehler said that he still mainly uses wet plates, except when he has a very lively baby or a dog to take, we think there is every probability that he will at some future time take a leaf out of the British book and turn wholly to dry plates. The public now will have quick pictures. As to pyro. or oxalate: that will find its own level. We cannot avoid thinking that the professional verdict on this side of the water is almost wholly for pyro.

We do not believe that the following picture, extracted from a correspondent of *Anthony's Bulletin*, will be considered to represent the character of English dry plates, however it may depict the sins of which American plate-makers may be guilty:—"It is dirt everywhere. Not so bad now as it was some time ago. They are improving; but yet there is room. Probably a bubble will appear across the eye either in plate or film, or a long hair from some man's whiskers; then a lump of hard gelatine on one ear. Sometimes transparent veins run right across the features or dress. . . . . The emulsion is not filtered clean, or the bottom ones of the batch are coated—dirt and all. Some of the plates in the same box are clean. Why are they not all so? Today I had a plate spoiled on account of its not fitting the holder, and the next plate was too small. On the next plate the packing had dropped down across the middle of the film and showed itself in the development. All these things could be improved upon by a little careful manipulating."

THE "HAPPY MEDIUM;" OR, DARK-ROOM ILLUMINATION.

IN THREE CHAPTERS.—CHAPTER II.

In my last communication on this subject I related an experiment by which I had proved to myself that canary medium was as safe a light filter as a singly-flashed ruby glass, and I also stated that having had the four square feet of my dark-room window fitted with Mr. W. E. Debenham's green "cathedral" glass, and having found the light therefrom not only unpleasant, but for me insufficient, I returned to my old plan of yellow glass and double-flashed ruby glass—both clear. My experiments also showed how much the addition of a diffusing element to a clear red glass enhanced the safety of the red glass. On this diffusing character of ground glass, matt varnish, and the grain of paper I place the highest importance. The spectrum of a glass is not altered in character by such diffusion, but it is considerably dimmed in power.

With my ruby glass *au naturel* the small print could be read at seven feet distance; the addition of a very thin coat of matt varnish so dimmed the illumination that the print could not be read beyond four feet. According to the law of the intensity of light this gives the effect of the extinguishing power of the matt varnish at a high figure, the intensity of light transmitted by clear ruby being as forty-nine to sixteen of the varnished glass at equal distances. This simply means that the diffusion of the ground surface or grain of the paper amounts to so much opacity. I think it is the diffusion produced by the thickness and grain of the canary medium that gives its surprising safety, for to me it is surprising.

Mr. Debenham's glass, too, is not ordinary transparent glass, but glass of the translucent kind seen in church windows and other places where people are not intended to look out, and where the light has to be diffused so as not to shine too strongly on the worshippers' or auditors' faces or into their eyes. In greenhouses nearly the same kind of glass may be found, the object being, as before, diffusion of light and the prevention of strong rays of direct sunlight impinging on the plants. I cannot see why Mr. Debenham uses *green* glass in particular. I may be wrong, but I think any other equally diffusing glass would be as safe, and I am certain any other kind of glass would be more pleasant to me. When I ordered the glass for Mr. Debenham's combination I got three samples sent. Of these, wishing to give the matter the most satisfactory trial, I chose the darkest green. This may account for my not seeing well, my window facing the north. As I said before, I have a dislike to anything having a tint bordering upon green, and of all the tints of green I dislike most the yellow tints. Probably hand in hand with dislike goes weakness of vision in the antipathetic colour of light. This brings me to another view of the subject in hand, and a very important view—the effect of the colours on the eye.

A considerable number of gentlemen assume—without reason, as I contend—that a red light for the dark room is more hurtful to the eye than a yellow or yellowish-green light. Even if these gentlemen are correct with regard to their own particular eyes, they have no right to apply the rule to the eyes of other people. In a subdued light of any kind the pupil of the eye dilates, the supply of blood to the retinal vessels diminishes, and on a sudden access of bright light the pupil suddenly contracts to regulate the supply of light in response to a reflex stimulus; a rush of blood to the vessels takes place, and there is no wonder if disagreeable sensations arise. This, I maintain, arises not from the colour of the dimmer light, but from its scarcity and the subsequent sudden access. Nothing hurts my eyes more than the sudden turning up of a gas in a previously-dark room. Let anyone try turning a gas jet quickly up and down, about twenty times per minute, watching the light all the time. I give a quotation from the letter of a brother of mine—a physician in London—who has paid some attention to the study of the eye. He had evidently misunderstood my own theory on the matter; but that is of little consequence so long as we arrive at his. The excerpt is from a private letter to me, and thus, possibly, not so carefully worded as it might have been had he known it was to appear in these august columns. It will be seen that his conclusion does not entirely coincide with mine; but my object is to get at the truth and not to nurse a pet argument on a diet of falsity. Here beginneth the extract:—

"About photographic light: pure yellow light is in itself more directly irritating to the retina than any other. The shades are irritating in proportion as they approach yellow. I know an artist of educated visional sensibility who says that certain colours, especially 'reds,' pain him, and there is no doubt it is so. I tested him, and there was always yellow present. I don't think the thermic properties associated with red light can in any way influence the retina, which is liable to far greater changes of temperature without appreciable impairment. So far as the colour of the light goes I am with you. [My proposition to him was: Red light does no more harm to the eye than any other light under similar circumstances.—A. P.] But I can't agree that contraction of the pupil, on coming into bright light, can of itself cause dimness of vision. On the contrary, its effect would be to limit the field of vision, but not improbably to give increased detail within that field. I would suggest the following theory, viz.: that the retina in the dark room, being comparatively passive, receives comparatively little blood; that when over-stimulated by the sudden flood of white light a corresponding excessive 'rush of blood' to the retinal vessels occurs; that the blurred images are counterparts of the buzzings heard in the ears when congested; and we know that in feverish persons with congested retina the images are blurred just as they are in anæmic brain conditions when the balance of the circulation is deranged in the other direction. N.B.—The parts of the brain for the action of the pupil and for the regulation of the retinal blood supply are totally distinct."

In a supplementary letter on the same subject my brother, who had meanwhile consulted a professional specialist (Mr. Marcus Gunn) as to the matter of his previous letter, wrote to me as follows:—

"The thermic properties of light are destroyed by passage through the liquid 'media' of the eye, viz., aqueous and vitreous humours. On the whole, my views accord with your own that the eye disturbance will be proportional to the difference between the light of day and the 'dimness' of the dark room. There is a very great opening for idiosyncratic difference both as regards mere sensitiveness and sensibility to certain qualities of coloured light."

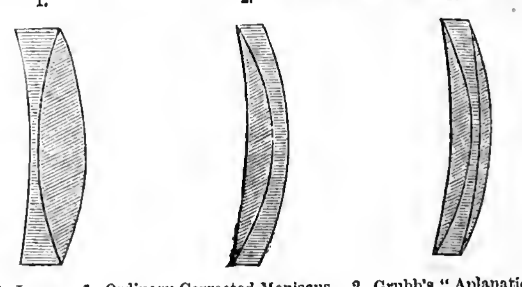
Now I am not too proud to confess that these letters, more especially when backed by an authority of Mr. Gunn's calibre, gave me very great pleasure. I had arrived at certain conclusions, and spoken them boldly and publicly, before I noticed the remarks of Dr. G. A. Herschell in your issue of November 23rd, 1883. Reading the article by Dr. Herschell I got what I may call a "facer" at first, but barring his statement as to the peculiar dangers of red light, which I do not find his own arguments to bear out, I failed to see that his article helped us out of our trouble. He condemned red light certainly, but he condemned dim light of other kinds almost as completely; and, considering that we must for plate-manipulation modify our light in some way, I fear he left us just where we were. He does not recommend any light in particular, so that the gist of his remarks is—"Give up photography or run the risk of damaging your eyes." I admit at once—who does not?—that it would be better if we could work in daylight, but we cannot; and our business is to find a light suitable for our work and as little damaging to our eyes as possible.

All the discussions before learned societies of late, all the changes made and expense incurred in the lighting of dark rooms, have hung on the assertion that red light is more injurious to the eyes than other lights, or on a one-sided and vicarious statement that yellowish light is the most pleasant to work by. I for one am now satisfied that my own original ideas were correct—not only that I prefer a red to a yellow light, but that my red is less hurtful than the vaunted yellows. I wish for my own sake I had thoroughly worked out and investigated these matters long ago, and I regret that I did not sooner give my opinions to the readers of this Journal; but I feel that late as I am in the field—"Better late than never." Even since I wrote the first "copy" for these pages evidence has been pouring in and experiments have multiplied, so that what I meant at first to be an article in one chapter has swollen to two chapters, and as I can take no more space at present I must even add a third. ANDREW PRINGLE.

ON LENSES.*

Of single lenses there are three distinctly-marked varieties. The first is the ordinary corrected meniscus. This is the well-known single landscape lens. The two faults in it are, that a small diaphragm is necessary in order to correct its spherical aberration and give good definition, and that it gives distortion. To correct to a certain extent the first of these evils, Mr. T. Grubb, in 1857, introduced what he called his aplanatic lens. It is not aplanatic, but the method of correction he

1. 2. 3.

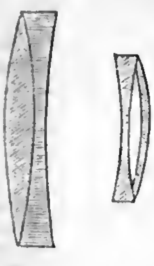


Single Lenses—1. Ordinary Corrected Meniscus.—2. Grubb's "Aplanatic."—3. Dallmeyer's Single Lens.

* Continued from page 283.

employed—placing the negative lens at the convex side—mitigated spherical aberration to such an extent that he thought it entitled to be called "aplanatic" in comparison with the ordinary single lens. It may, therefore, be worked with a larger opening. The panel portraits now shown were, with one exception, taken with this instrument. Dallmeyer's single lens consisted, like some of Dollond's telescope objectives, of a negative lens between two positive ones; but the curves are, of course, quite different, being calculated for marginal definition and flatness of field.

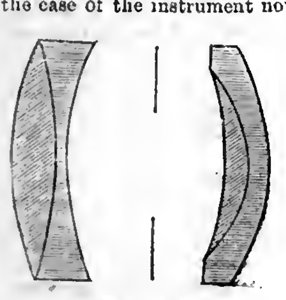
The so-called "orthoscopic lens," introduced in 1857, was constructed from calculations made by Petzval at the same time that he was engaged upon the portrait lens. The front part is identical with that of the portrait lens; but the back consists of a dispersing lens, so that the whole instrument is longer in focus than the front part alone. It was a curious misnomer to call it "orthoscopic," seeing that it necessarily gives distortion, although, from the diaphragm being at the back, this distortion is in the contrary direction from that given by the single lens. There were some good points about the instrument, and it is quite possible that if it had been introduced since the advent of the rapid gelatino-bromide process, it would have found more favour, especially for large portraits, than it has done. I should not be at all surprised to see it or something modelled upon it come into use. Sufficient care was not always taken to make the correction for actinic rays perfect. In one that I possessed it was necessary to shift the camera back nearly half-an-inch, but when this was done a very good portrait might, in a quick light, be taken even with collodion.



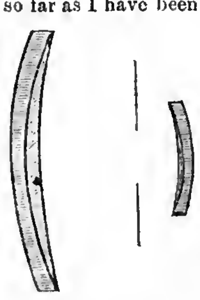
Petzval's Orthoscope.

Triplet lenses were introduced in two ways. One was as an instrument for obtaining architectural views without distortion; and another was an adaptation, to the portrait lens, of a concave glass in the place of the diaphragm for the purpose of lengthening the focus and flattening the field. Slater, in 1858 I think, made instruments of this kind for sale. As an occasional expedient a similar device had long previously been employed. Derogy made many of such instruments, one of which is on the table. Triplets have now been generally superseded by doublets.

To obviate the distortion caused by the single lens many double combinations have been devised. In these, the diaphragm being placed between the lenses, the distortion caused by one lens is counteracted by distortion in the contrary direction produced by the other lens. The first of these to come into any general use was the globe lens of Harrison, brought out in 1860. This supplied such a much-felt want—that of a lens of wide-angle without distortion—that it was much used; but the exact globe form was found to favour the formation of a patch of reflected light in the picture called a "flare" spot. Some five years later Ross introduced a lens which achieved great popularity, and was really so useful an instrument that it deserves some special mention. The front lens was a meniscus corrected in the usual manner, but the back lens had, like the Grubb single lens, the negative lens outwards. A description of a doublet with a back lens of this character, made by A. Ross, was published as long ago as 1846. The instrument had a wide angle of light; but this could be made even wider by setting the lenses a little closer together, as has been done in the case of the instrument now shown, and this, so far as I have been able to ascertain, without in any way injuring its definition. The great angle of light admitted permits of the lens being used even for tall buildings by raising the camera front without tilting the back, and I think it is to be regretted that it is no longer manufactured. They appear to be well appreciated, as I notice that when any are in the hands of the dealers they are marked at good prices. Dallmeyer's wide-angle rectilinear is a doublet which, constructed on different principles, works very similarly.

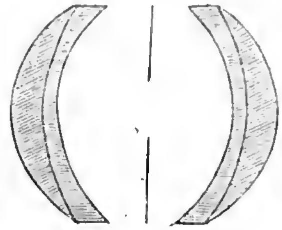


Ross's Doublet.



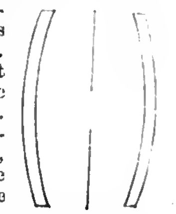
Dallmeyer's Wide-angle Rectilinear.

Busch's pantoscope is a lens partaking of some of the characteristics of the three last-mentioned lenses. It has a very wide angle, and is a very useful instrument. It differs from the globe lens in that the exterior surfaces do not form part of one sphere. I have not found "flare" when using it. A lens that I have not had the opportunity of examining is a doublet by Morrison, of New York. An excellent judge, however, Mr. J. Traill Taylor, gives a favourable account of it. The striking peculiarity of this instrument is that one of the elements, the back one, is single, all the correction being performed by a flint in the front combination. Some eighteen or twenty years since I constructed an experimental lens, the front of which was a single meniscus and the back was an objective out of an opera-glass, altered by having the flat side ground concave. This lens gave an enormously-wide field, but required the use of a very small diaphragm.



Busch's Pantoscope.

Before proceeding to the consideration of the more modern doublets it is worth while to notice two which I believe have gone out of manufacture. These are the periskop of Steinheil and the Zentmayer lens. Their particular interest consists in the fact that, being constructed of uncorrected crown lenses only, something similiar to them can easily be improvised. Steinheil's periskop consisted of two similar meniscus crown lenses placed near with a small diaphragm between them. After focussing, the camera back had to be brought nearer to the lens by $\frac{1}{40}$ of the focal distance. The field was very flat and the angle included large. Zentmayer's lens was constructed on similar principles, but was furnished with two diaphragms, the larger of which was to be used for "convenience of light" in focussing, and the smaller one for the exposure. It was introduced as a lens not requiring correction, although made of one medium crown glass only; but this paradox was only apparent, not real.



Steinheil's Periscope.

On looking at the diagram of spherical aberration *(fig. 2)* [page 264], it will be seen that the general approximate focus of a lens possessing this characteristic, when used with large aperture is shorter than the focus of the same instrument when used with a small diaphragm. Zentmayer's lens had great spherical aberration, and it was, therefore, only necessary to make the focussing and exposure diaphragms of such sizes as to alter the focus in the same proportion as the chemical focus was shorter than the optical one. I have here a lens that I had constructed some years previous to the Zentmayer being brought out, when I was desirous of photographing subjects occupying a wider angle than I could get with the lenses then to be purchased. The radii are about as six for the convex and seven for the concave surfaces, and the distance of the lenses apart as four. If the lenses are of large diameter in proportion to the focus an enormous angle of view can be obtained.

This is the lens which within the last week your Secretary, Mr. J. J. Briginshaw, has had for the purpose of photographing a tall building in the city which he could not with an ordinary lens do, on account of there not being space to retire with the camera. He has brought the negative with him, and you will be able to judge of the occasional usefulness of such an instrument. The camera was used level, and the front much raised. From the point opposite to the lens five inches can be measured to the corner of the plate. This gives a circle of ten inches. The focus of the lens is about three and a-half inches. The back was not altered after focussing, the correction, as with Zentmayer's lens, being made by the insertion of the diaphragm.

W. E. Debenham.

(To be concluded in our next.)

A FEW REMARKS ON THE USE OF IODISED BROMIDE OF SILVER EMULSION IN THE ESTABLISHMENT OF HERR KROH.

Professional photographers often make the not unfounded complaint that, when working with bromide of silver emulsions and ammonia silver oxide, the high lights and delicate shades are wanting in the clear parts; and even though these may be present in many cases in the negative, it seems to be difficult to get them to come out in the print. This is a fault against which many experimentalists have already tried to protect themselves by incorporating iodide of silver with the bromide of silver emulsion. In Herr Kroh's studio we have made the most various experiments, using various proportions of iodine and of bromine, as in the collodion process; that is, ascribing to the presence of the bromide of silver the highest sensitiveness to dark rays (that is to say, to details in the shadows), and the opposite to iodide of silver sensitiveness to the bright rays of light (that is to say, for the intensity of the light). Certain advantages were attributed in the collodion process to such different strengths of iodising. After many fruitless experiments we succeeded (as the pictures shown at the meeting of the Photographic Society of Vienna, on the 3rd October last, bear witness), with the formula here given, in getting modulation, brilliancy in the whites, and depths and shadows rich in details, combined with great sensibility.

Place in a retort of two litres' capacity—

Bromide of ammonium	24 grammes.
Bromide of potassium....................	24 ,,
Iodide of potassium........................	5 ,,

Dissolve these salts in 500 c.c. of water, then add eighty grammes of hard gelatine, and leave it to soften for a quarter of an hour. Meanwhile dissolve in a separate vessel sixty grammes of nitrate of silver in 500 c.c. of water, and in the usual way, as recommended by Dr. Eder, add ammonia until the brown precipitate which forms at first is redissolved; that is to say, until the silver solution has become clear again. Now place the flask containing the gelatine solution in a water bath at 55° to 60° C., and leave it there until the gelatine is completely dissolved; then add the ammoniacal silver solution to it, a small portion at a time, meanwhile stirring vigorously and continuously (otherwise the bromide of silver would be apt to be thrown down instead of remaining in suspension). Finally, digest the mixture for three-quarters of an hour at about 50° to 55° C., shaking at short intervals and pouring a trial plate every quarter of an hour, in order to examine it at the light and to observe whether the emulsion has been converted into the yellowish-green modification. When a sample has passed into that condition the digestion may be regarded as ended; the emulsion is poured into a cup to stiffen, squeezed through canvas, washed in eight to ten changes of water in the course of two hours, and the nodules, after being placed in a bag, hung up to drain over night. Next morning place the drained nodules in a beaker in order to melt them, adding 250 c.c. water, which was omitted during the preparation, in order to facilitate the washing, as well as in order to be able to reduce the quantity of water to be added in case the emulsion should have absorbed much water during the washing. This can easily be computed, and the excess of water absorbed during the washing can be deducted from the quantity of the final addition of water.

Those who wish for still more powerful negatives may make the following addition before filtering:—One gramme of sublimated iodine is dissolved with iodide of potassium in ten c.c. of water; about eight drops of this solution are added in order to make the emulsion work more powerfully. For reproductions, line drawings, and plans this addition may be doubled or trebled according as one wishes to have more or less dense negatives. CH. SCOLIK.

—*Photo. Correspondenz.*

THE DEVELOPING-ROOM LIGHT OF THE FUTURE.

ONE omission in my last communication might lead to some fogging of plates. The size of the developing-room was not stated, and the remarks about no top to the candle-illuminated cardboard lamp being necessary applied only to those used in large rooms. A lamp without a top in the little developing dens—once, if not now, common in England—would probably lead to fogging, if but a short distance intervened between the candle flame and the ceiling and closely adjacent four walls. In small rooms a bit of yellow or green or white paper should be laid on the top of the lamp, and care taken so to fold it on the top of the lamp nearest the developing dish that its lower surface cannot reflect light down on the dish. It may be so torn as to leave a rather large hole on the top part of the lamp away from the developing dish, so as to permit the escape of the last products of combustion.

Among coloured single-layered screens of whatever material made there is not one in a hundred or one in a thousand which will give in its purity but one of the seven primary colours of the spectrum. The late Professor Allen Miller's large range of experiments prove this. A summary of these experiments is published in some of the earlier editions of his great work on "Chemistry"—perhaps the most valuable book of reference on chemistry extant, next to the larger works of Gmelin and Watts. I prefer the old editions of Miller to the new, though the latter are more scientifically arranged, so as to form almost a new work. The editors would have done better to have put what they had to say in a separate book of their own, instead of bringing out a hybrid work under the name of the great departed.

As it is unlikely that the best lamp of the future will possess but a single-layer screen, spectroscopic examinations of a limited number of single screens only are likely to be of little practical value. Two bad single screens superimposed are indeed often likely to make one of the best double screens obtainable; that is to say, the two layers may separately let plenty of fogging light through, but the one may have just the power of cutting off the rays which do mischief through the other, and the two superimposed may let more useful light through than any screen in which attention has been directed only to the power of actinic absorption of a single sheet. Hence the value of the power, when it can be obtained, of selection from many green and yellow samples of oil silk. With twenty varieties of colour of those silks on a polychromatic negative an experiment can be tried at one blow on 400 superimposed pairs, on a single half-plate, at a cost of but a few pence, and the best pairs ascertained. Then the *auxiliary* power of the spectroscope could be brought in to find out the defects of the best pair (which defects, however, would probably be of little practical importance), and then a third oil silk layer with scarcely any colour at all in it might be found, but which would just cut off the few feeble rays theoretically mischievous. Probably no screen is the best which permits the shape of the flame to be seen through it, and perhaps but two thicknesses of oil silk would let it be seen. Then more layers of other varieties of green and yellow could be added. Thus layer upon layer of new colours could be laid on—each layer also introducing more of the Starnes' lamp principle—at the same time that the variations in colour empirically narrowed down the escaping light more and more to a pure colour of the spectrum, preferably green *plus* a little yellow deterioration. Probably the best light will be that in which enough layers of coloured films are laid on to prevent the shape of the flame being seen through the composite screen and no more. Of course the papers or silks must not be gummed together where the light shines through them—a very dangerous thing to do in the case of papers especially. A man who thinks he can improve his paper screen by rendering it more transparent, by gum or otherwise, usually labours under a fatal error. W. H. HARRISON.

Lucerne, April 26, 1884.

FOREIGN NOTES AND NEWS.

A COLOSSAL ALBUM.—THE LATEST PARISIAN NOVELTY.—A CHECK TO PORCELAIN PAINTING.—HERR GIESSE ON PHOTOGRAPHIC PORTRAITURE IN AN ORDINARY ROOM.—PAPIN'S DIGESTER AS AN EMULSIONISER.—THE ACTION OF LIGHT UPON FERROUS OXALATE.

ACCORDING to the *Archiv* a large album is at present lying in the shop of Herr Collin, court bookbinder, Berlin. It is to be presented to Herr Henry Villard by the German guests present at the opening of the Northern Pacific Railway, and contains their portraits in boudoir size.

It is now the correct thing for a Parisian dame to have her photograph taken at home. *Une dame du haut ton* who has made up her mind to be taken sends a telegram to some photographer who makes a speciality of this branch of the business, and, *presto!* the thing is done. Consequently, fashionable people no longer tell their servants to say "not at home" when a bore calls, but prefer to say—"Madam begs you to excuse her; she cannot see anyone, as she is having her photograph taken!"

Herr Giess, in the *Archiv*, makes a few remarks respecting photographing in rooms. He uses a large wall mirror (about five feet high) as a reflector to help to lighten the shadows. The first time he used it he simply leant it against a table, the result being that the rays of light thrown by it were projected upwards instead of in the opposite direction, thus causing the shadows under the chin, the nose, and round the eyes of the sitter to disappear, or, at anyrate, to be too much modified. He then got a carpenter to make a frame for it set upon casters, which allowed him to move the mirror backwards and forwards or to place it at any angle desired. With a portrait lens, a three-inch stop, and moderately-quick dry plates, when using the mirror he gave an exposure of from fifteen to twenty seconds in an ordinary room. An energetically-working pyrogallic acid developer was found most suitable.

The painters on porcelain in the Thüringian Forest have, it is said, received a severe check. The *Photographische Gesellschaft* in Berlin, which has acquired the right of publishing copies of the paintings of many celebrated masters, have lately seized in one small Rhöneland town a number of copies upon porcelain and the steel plates from which they were copied, as infringing their rights; and a Berlin firm which sold unauthorised reproductions in oil colours of some copyright pictures has been condemned to pay a fine of 100,000 marks—say £40,000 or £50,000.

According to Graeter, in the *Photo. Correspondenz*, the length of time that gelatine emulsion has to be cooked may be shortened by using a Papin's digester. If the vapour pressure in it be equal to four atmospheres the temperature will be about 140° C., and then cooking for a quarter of an hour should be as effective as cooking for an hour at ordinary atmospheric pressure. At such a temperature soft gelatine would be destroyed.

In the *Comptes Rendus* M. Lemoine relates that he has taken mixtures of oxalic acid and chloride of iron in solutions of various concentration and of different quantitative proportions, exposed them to sunlight always in films of the same height and thickness for the same length of time, and observed the decomposition by measuring the carbonic acid evolved. The rapidity of the decomposition (the intensity of the light not being taken into account) is at first almost constant, and continues so until about one-half of the mixture is decomposed; afterwards it decreases. It is, however, greater if the oxalic acid and the chloride of iron solutions have each been previously and separately exposed to light for a considerable time. The decomposition also proceeds more rapidly when the solutions are dilute, or when they contain an excess of oxalic acid. The latter then only acts as a diluent. On the other hand, the decomposition is retarded when the mixture contains excess of chloride of iron, as that absorbs the rays of light.

PICTURE-MAKING BY PHOTOGRAPHY. By H. P. ROBINSON.
London: PIPER AND CARTER.

THIS latest work from the pen of Mr. H. P. Robinson will be welcomed by all who are interested in the production of artistic effects, containing, as it does, the experiences of one who may be accepted as the English representative of art-photography. The author's aim may be described in his own words from the preface:—

"I fear that a great deal more will be found concerning my own personality and productions than a modest writer would willingly admit; but this cannot easily be avoided. The nature of the information to be conveyed and the lessons to be inculcated demand that I should teach the results of my own experience, and suggest that the pictures which have been the outcome of that experience would be the most suitable illustrations. It will be evident that pictures which have been actually produced by photography will better show the peculiarities and limitations of the art than any other method of illustration."

And so Mr. Robinson proceeds to discuss in a chatty way the different branches of his subject, not even overlooking the matters of "Gelatine Plates and their Uses," and "Our Tools." In the chapters which deal with the selection and treatment of subjects and the introduction of figures into the picture, anecdotes are told of the manner in which many of his best-known works were conceived, reproductions of such works being introduced as illustrations. The work contains four full-page illustrations, by Sprague and Co.'s "ink-photo." process, of some of Mr. Robinson's best-known and most recent successes, besides a large number of woodcuts taken from other of his works as they happen to serve his purpose. The book should be in the hands of every photographer.

PHŒNIX INSTANTANEOUS SHUTTER.
Leeds: REYNOLDS AND BRANSON.

WE had occasion to notice this shutter some twelve months ago, but it comes before us now, if not in a new form, at least with modifications which so alter its working that it is practically a new shutter. It still consists of the two essential parts—the rising flap and the drop; but, in place of the adjustable spring which actuated the flap in the older form, we have now a weighted lever adjustable to any variation of exposure, from (say) a-quarter of a second to (in combination with the rubber band on the "drop") any degree of rapidity.

The alteration is in many respects an undoubted improvement. Springs are at best unreliable elements in any compound; but the simplicity of the weighted arm now substituted is beyond cavil, and its efficiency equals its simplicity. Its adjustability within certain bounds is also an important feature. The alteration in the motive power of the flap portion of the shutter does not interfere with its use for slow exposures; and an arrangement is provided by means of which the drop shutter is kept out of action while the flap is manipulated alone to give exposures of any duration.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held on Thursday, the 1st inst., at the rooms of the Society of Arts, John-street, Adelphi,—Mr. Edwin Cocking in the chair.

The CHAIRMAN said:—It is my most painful duty to take the chair on this first meeting of the Society after the lamented death of our President, whose loss we all so deeply deplore. For twenty-five years this Society has existed under one President, and during those long years we have not only entertained feelings of deep respect for him but, I may say, love. I think it will be admitted that that feeling arose from one great characteristic of our late President, which was that of genial, warm-hearted sympathy. He was a man who was animated with the spirit of kindness, which smoothed down angularities, and brought to light the latent good in every one. After listening to his remarks we felt that our tone of mind had been elevated; and, besides the brighter view of things which his words inspired, we felt grateful and our hearts warmed towards the man who, with such unflagging interest, had presided over this Society ever since its formation.

Mr. F. A. BRIDGE:—It was thought that before the meeting took a formal character it would be well that we make known that it is our desire to send a letter of condolence to the relatives of our late President. As a matter of strict etiquette we ought tonight to have appointed a Chairman to read the minutes of the last meeting, and that being done should have adjourned; but we had in our hearts the thought of our late President, and remembered that with him duty was always the first consideration. Besides this, it happens that Mr. Macbeth is in London at present, but cannot be here in a month's time, and so we decided that the meeting should proceed. Had we occupied the whole evening in proposing and seconding a vote of condolence to the relatives of Mr. Statham we could have done no justice to our late President. In the *South London Press* there is a *résumé* of the life of Mr. Statham which I would commend to your notice. I think the relatives of such a man have much to be proud of, and that even we who have met him here have also the same feeling. I would have the meeting rise, as it were, to authorise me to send a letter of condolence to our late President's family.

The minutes of the previous meeting having been read and approved,

Mr. NORMAN MACBETH, R.S.A., was called upon to read his paper, entitled *Notes on the Composition of a Picture*. [See page .] Mr. Macbeth proceeded to say:—I would take this opportunity of expressing how deeply I sympathise with you in the peculiar circumstances in which you are placed. I certainly miss very much tonight the presence of your late President. Although I had no personal interview with him, I may say that I knew him through your Hon. Secretary. I know that in such small efforts as I have made for you he took a deep interest, and that his acknowledgments were most gratefully received by me.

Mr. Macbeth having concluded his paper, showed a number of photographs and sketches as illustrations of his remarks.

A vote of thanks having been carried by acclamation,

The CHAIRMAN said he hoped some questions would be asked.

In reply to a question, asked by a Member, with regard to the proper ratio to exist between focal lengths and size of plate in photography,

Mr. MACBETH said that the question being a purely optical one he would not take it up. He would say, however, that he had a strong predilection for the single lens.

Mr. E. W. FOXLEE asked what distance there should be between the lens and the sitter in taking a portrait.

Mr. MACBETH said that the distance should be considerable. He hoped to get a lens which would permit of his using the whole thirty-five feet length of his studio. It would be a single lens.

Mr. J. TRAILL TAYLOR observed that the perspective given by a lens did not depend on its form but on its focal length merely.

Mr. F. YORK said it was important first to fix the point of view, then to use whatever lens took in the necessary angle. It was common to recommend a focal length slightly greater than the length of the picture. He thought that a focal length equal to the diagonal of the plate would give good results, but they might use much greater focal lengths. Nevertheless, the use of wide angles was at times unavoidable.

Mr. MACBETH thought the photographer should not commit a breach of truth merely for the sake of convenience.

Mr. BRIDGE remarked that this was a matter more easily managed by painters than by photographers.

Mr. TAYLOR said that he would like to hear Mr. Macbeth's opinion on the correct position of the horizontal line in the case of portraiture. It should, theoretically, be at least as high as the eye of the observer; but at times it was lowered to within twelve or fourteen inches of the ground.

Mr. MACBETH had found it necessary, in painting figures in the studio, to take the different portions from different points of view, the head being taken from a high point of view, and the lower portions from a lower point of view.

Mr. HARRISON said that the *proportions* of a figure varied no way with the focal length of the lens used, so long as the point of view remained fixed. The size only varied.

The CHAIRMAN remarked how great a benefit it would be to members could they have an opportunity of going out for practical work with such a man as Mr. Macbeth. He asked for a formal vote of thanks to Mr. Macbeth, besides the informal one which had already been passed.

Mr. MACBETH felt flattered by the reception his remarks had met with. He looked with no jealous eye on photographers, and thought that painters in general were ceasing to do so. It only remained for photographers, whilst adhering to the principles which he had laid down, to display their individuality, for which there was ample scope. He hoped it would not be the last time he might be present at a meeting of the South London Photographic Society.

It was mentioned that Mr. C. R. Pancoast, of the Photographic Society of Philadelphia, was present, and that gentleman being called upon, thanked the meeting for the welcome which had been given to him. He had been travelling in India, and had taken a number of negatives of the exhibits at the exhibition there. He hoped to send prints of them to the South London Photographic Society.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting of this Society, held on the 1st instant, the chair was occupied by Mr. W. E. Debenham.

The subject of diffraction in connection with photographic optics being mentioned.

Mr. A. Haddon said it could only be noticeable when extremely small diaphragms were used. The pinhole used instead of a lens by Mr. A. L. Henderson to produce the photographs which had been shown at a previous meeting had not been small enough to produce any perceptible amount of diffraction, and the diaphragms used by photographers were always much larger than that pinhole.

Mr. J. Cadett remarked that Professor Stokes had stated that if the diaphragm were in the optical centre of the lens there would be no diffraction, however small it might be.

The Chairman said that when a pinhole was made in any substance the hole took the form of a short tube. The effect of light reflected from the sides of such a tube might have been mistaken for that of diffraction.

Mr. F. W. Hart remarked that it was sometimes desired to back a negative in part with a semi-transparent substance, and *papier minéral* and matt varnish were used for that purpose. Instead of scraping away the matt varnish from those parts of the negative that were required to print more strongly, the varnish might be rendered transparent in those places by letting the vapour of ether fall upon it, a soft edge instead of a sudden one being produced. He illustrated this, and explained that it was better not to use a very strong ether for the purpose, or, if such were used, to mix some alcohol with it.

Mr. J. Barker inquired whether anyone had succeeded in producing a thoroughly-good matt varnish by using the published formulæ. He had not been able to make it as good as that which was sold.

Mr. Hart said that a formula for matt varnish was of no more use than a formula for collodion. It was necessary to take into consideration the different characteristics of the various samples of material that were employed.

Mr. Barker remarked that, notwithstanding the remarks in the photographic journals, he was still of opinion he was right in stating that with lenses of equal focus and size of diaphragm, the lens of large diameter would be the quicker. He also held that some lenses possessed much more depth of focus than others, aperture and focus being equal. On mentioning this to a neighbouring photographer that photographer confirmed his opinion, and gave him the *carte* which was now shown in support of his theory. It would be seen that the figures and background were sharper than it was usual to get both together.

In reply to Mr. Barker,

The Chairman showed on the black board that with lenses of the same focus and size of diaphragm, increasing the diameter of the lens would have no effect on the illumination of the centre of the picture. Towards the margin it would have an effect, unless the smaller lens were placed nearer to the diaphragm, when, again, the results would be equal for speed. As to the idea that the particular lens of which the work was shown, possessed any depth of focus more than was due to the size of its stop, the claim only showed the necessity there was for showing how groundless was such an idea, although so commonly entertained. The specimen photograph produced, to be of any value as evidence, should have been accompanied by information as to the size of the diaphragm and the length of focus of the lens; and it would be more conclusive to have taken another photograph from the same spot with another lens not supposed to possess the same characteristics.

Mr. J. Cadett could see nothing in the photograph produced by Mr. Barker to lead him to infer anything remarkable in the lens with which it had been taken.

THE POSTAL PHOTOGRAPHICAL SOCIETY.

A committee was held on Monday last, the 5th inst., at the Chambers of the Honorary Treasurer, 3, Plowden-buildings, Temple.

After the minutes of the previous meeting had been read and confirmed, the following gentlemen, provisionally admitted since last meeting, were declared duly elected:—Messrs. Chas. B. Stones, Brighton; George Smith, Dudley; John Kinder, Epsom; John A. Fothergill, Darlington; G. Percival Smith, Tunbridge Wells; E. Openshaw, Manchester; and C. W. Kingdom, Cirencester.

The prints sent in for Competition IV. were inspected, and the Committee decided that the value of the prizes should be as follows:—Class I. First prize, £1 1s.; second prize, entrance fees, 10s. 6d. Class II. First prize, £1 1s.; second prize, entrance fees, 12s. 0d. Class III. Prize of 10s. 6d. Class IV. Prize of £1 3s. (donation by Mr. Ticehurst).

The two first classes will be found to contain some very good work; the two latter, however, are but poorly represented so far as quantity is concerned. The Committee did not, therefore, feel justified in giving second prizes.

The next competition was fixed for the 1st of July next, in the following subjects:—Class I., landscape (including architecture); Class II., portraits—groups or figures; Class III., interior.

It was decided that three competitions per annum should be held in the future, pictures to be sent in by the 1st of July, the 1st of October, and the 1st of May, the subjects to be announced at the general meeting in June.

As in each album now issued there is a small competition (in accordance with Dr. Day's motion at the last meeting), it was resolved, on the motion of Mr. Pocock, that henceforth no greater number of prints from the same member shall be inserted in any one album than would fill three pages thereof, and that a separate noting slip for each such quantity should be filled up by the member. [This would be twelve quarter-plate, six half-plate, or three whole-plate pictures.]

The voting book, having been sent to all the members, was next considered; and the Committee found the result of the voting to be:—1st. That the competitions be continued as at present.—2nd. That the annual subscription to the Society be raised to 7s. 6d.—3rd. That an entrance fee of 1s. 6d. to the competitions should be continued.

Particulars of the amount subscribed by the members towards a testimonial for the late Hon. Secretary were given by the Hon. Treasurer, who was authorised to order a Rouch's $8\frac{1}{2} \times 6\frac{1}{2}$ camera, Dallmeyer's W.A. lens and tripod, to be presented to Mr. H. H. Cunningham, B.A., in the name of the Society.

The question of secretaryship was for the present postponed, Mr. Baylis stating he was prepared to discharge the duties connected therewith until the general meeting in June.

The meeting was then adjourned.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of this Society was held at the Association's Studio, on Wednesday, the 23rd ult.,—Colonel Playfair, Vice-President, in the chair. After the usual preliminaries,

The Chairman called upon Mr. E. Brightman to read his paper on *Rapid* versus *Slow Development*. [See page 294.]

The Chairman said that Mr. Brightman, having exposed two plates of similar sensitiveness—one for eight seconds and the other for eighty seconds—and developed both with successful results, had demonstrated that, so far as these experiments were concerned, slow development possessed decided advantages. He should like to have seen compared the development of two negatives correctly exposed—one by slow and the other by quicker development.

Mr. Brightman said that he should very probably bring such examples at a future meeting, and he thought the results would prove the superiority of the former mode.

The Chairman asked Mr. Brightman if he followed exactly the same practice with regard to under-exposed negatives.

Mr. Brightman replied that he did exactly, always using the same quantity of pyro.

The Chairman said that that appeared to him to quite oppose the usually-accepted law.

Mr. Daniel said that probably the effect produced was that of obtaining full detail at an earlier stage of the development, so that such detail was really worked up before the pyro. was sufficiently acted upon by the ammonia to produce much density in the high lights.

Mr. Tribe had generally considered that in developing an under-exposed negative it was desirable to lessen the amount of pyro.

After some further discussion, the next and first excursion meeting of the session was fixed for Saturday, the 17th inst.

A cordial vote of thanks, on the motion of the Chairman, was unanimously passed to Mr. Brightman for his interesting paper; after which the meeting was adjourned.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

The annual business meeting of the session was held in the Religious Institution Rooms, on Thursday, the 24th ult.,—Councillor Robertson presiding.

The minutes of the last meeting were read and confirmed. The office-bearers for the ensuing session were then elected and were as follows:—*President:* Councillor Robertson.—*Vice-Presidents:* Messrs. Robert Dodd and John Parker.—*Treasurer:* Mr. Geo. Bell.—*Interim Secretary:* Mr. J. Craig Annan.—*Council:* Messrs. J. Craig Annan, Wm. Lang, Jun., George Mason, James McGhie, J. Y. McLellan, and J. M. Skinner.

It was then arranged that an outdoor meeting should take place, and Cadzow Forest (the home of the Duke of Hamilton's famous white cattle) was suggested as the place, Friday, the 6th June, being the date. The arrangement of details was left to the Council and Mr. Falconer.

Some business of a private nature followed, and at the close of the meeting Mr. Falconer showed a number of very good lantern and stereoscopic transparencies and also a sky-shade. This was something like the upper half of a diaphragm, which was composed of slips of card, and which could be pushed up or down to the approximate shape of the sky-line. It was inserted in a slip in the front of the lens during the greater part of the exposure, and removed just before replacing the cap.

The meeting was closed with the customary votes of thanks.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

The eighth and last monthly meeting of this Society for the session was held in Lamb's Hotel on Thursday, the 1st instant,—Mr. J. Geddes occupying the chair. After the routine business had been disposed of,

Mr. Jno. Robertson read a paper on *Dark-Room Illumination.* Until lately he had scrupulously obeyed the injunctions accompanying dry plates and had worked in ruby light. As the result of some experiments, however, he had entirely discarded ruby and fitted up his dark-room window with two thicknesses of cathedral glass with a double sheet of orange tissue between. The illumination of his dark room was now all that could be desired, and he had never enjoyed such a perfect immunity from fog since the adoption of this light. The result was so satisfactory that he was fitting up the same light in his coating-room.

A hearty vote of thanks was awarded to Mr. Robertson.

One new member was admitted.

Mr. Walker, Broughty Ferry, kindly sent a collection of prints taken about 1856, which excited much interest; and the fact that in very few of them were signs of fading to be detected testified to the carefulness of the manipulation.

On the motion of the Chairman a vote of thanks was passed to Mr. Walker, and the meeting was adjourned.

PHOTOGRAPHIC SOCIETY OF VIENNA.

This Society met on the 4th March,—Dr. E. Hornig in the chair. The minutes of the previous meeting having been read and several new members admitted, the report of the Vienna Photographic Assistants' Society was read, and a subsidy voted to it, to be placed to the credit of the sick and superannuation fund.

The Voigtländer medals, awarded at a previous meeting to Lieutenant David and Herr Fokstein, were presented.

A number of instantaneous studies of landscapes, clouds, and plants, from Java, Borneo, and Sumatra, by an amateur, were shown by Herr Kramer, and a variety of other pictures, including lichtdrucks, were shown by other members. The Chairman showed some specimens of retouching from the studio of Herr Fernande.

Herr Haack called attention to the imperfect action of the springs which push up the candle in certain kinds of dark-room lanterns, and suggested remedies.

The question-box was found to contain two papers. In the first a member who had bought Kroh's rapid process inquired how he could dissolve gelatine in dilute alcohol, as that was a necessary part of the process.

Herr Scolik replied that the gelatine should be treated with strong acetic acid before the application of the alcohol.

The second paper asked what precautions were required in enamelling a picture so as not to wipe off the printing from the mount.

Herr Wrabetz said that the only precaution was to allow the varnish present in the ink, used as a cementing and transferring medium, to become dry before removing the mount.

The meeting was shortly after adjourned.

Correspondence.

May Meeting of the Photographic Society of France.—M. Audra's Experiments on Emulsion Made Before the Society.—MM. Thury and Amey's Instantaneous Shutter.—Communications by M. Scola.—On Residues.—A Photomicroscope.—M. Vidal on Ceramic Ornamentation by Photography.—Natural Colours Produced by Photography: Another "Canard."—The Late J. B. Dumas and the Rev. F. F. Statham.—A New Editor for Photographic Publications.—M. Liebert's Treatise on Carbon Printing.

The usual monthly meeting of the Photographic Society of France was held on Friday last, the 2nd instant,—M. Peligot in the chair.

M. Audra presented three proofs on glass made with the emulsion he manufactured in full gaslight the previous Friday evening. Not only had the cut-up and unwashed emulsion been made in full gaslight, but it had stood on the table upon which it was made until five o'clock the following day, thus being exposed to white light for several hours. The exterior had a grey appearance, but on being broken up he found it to be white in the interior. Nevertheless, being fearful, he doctored it by adding a solution of bichromate of potash and washed it thoroughly. The emulsion was free from fog, but he could not obtain intensity, and a good deal of rapidity had also been lost. These experiments were intended to show that emulsions, even though they may have been exposed to light during their manufacture, were not to be considered as spoiled; but altogether it appeared that the less white light they were exposed to the better.

I presented to my colleagues a double-action, rapid shutter, manufactured by MM. Thury and Amey, of Geneva, intended for binocular stereoscopic lenses, which is the first of that kind produced by them. The action of this shutter is well known to all. It consists of two strips of thin brass having each a round hole in the centre, and in order to make the exposure they slide one over the other in opposite directions. The centre of the lens is opened first, and then the hole becomes larger and larger until the full aperture is attained. The hole then diminishes in size until it is completely closed, and that in the centre of the lens. MM. Thury and Amey have chosen a circular hole, which resembles what is called in England the "eclipse" shutter, but constructed in a more elaborate manner. By means of a brake, which can be regulated by a screw, any rapidity can be obtained, from the $\frac{1}{200}$th part of a second to an exposure of two seconds. This brake was very much criticised by some members, and, in my opinion, not without good reason; for when the brake was fully put on the closing was obtained by fits or starts. I consider we have no need of a rapid shutter to give us an exposure of two seconds; that can be done watch in hand. What we require is a perfect instrument giving a true exposure from a fraction of a second (say one-half) to the $\frac{1}{200}$th part of a second, graduated correctly and not liable to vary or get out of order. Such an instrument is still to be constructed, and would secure a legitimate success for the designer. The lens of MM. Thury and Amey is placed in the centre of the lens, and for this reason the drum of the lens is to be cut in two, which is a great objection to many amateurs. This position is the most natural and logical for a rapid shutter, as the maximum of rapidity can thus be attained without difficulty, whatever may be the shape of the opening chosen. There is the choice of a circular hole (as in the "eclipse)," of a lozenge form, or that of a slit. The latter I adopted for my shutter, finding it better than either of the other two. Alas! the maker into whose hands I gave my patent, although an excellent clockmaker, built up an apparatus sufficiently strong and heavy for a steam engine, and thus neutralised all my efforts towards a perfect instrument.

M. Scola read a paper on the difference of rapidity in gelatino-bromide of silver plates having a brilliant or a matt surface. So far as I could glean, matt surfaces allow the reagents to penetrate more easily, and therefore the image comes out more rapidly, but at the end no difference whatever will be found. In order to cure Coignet's "pits," or eliminate grease from gelatine, M. Scola proposes to wash the gelatine in benzoline; for grease is only upon the surface and not in the midst, and very easy to dissolve by that system. M. Scola then discoursed about the best means to reduce residues. He gave the history of the electric battery composed of silver chloride, and counselled emulsion makers, if perchance an emulsion were lost, to make electric cells with the silver bromide, which would be a great saving of time and money. Electric bells could be established all about the premises and kept at a high degree of efficiency, and, at the same time, residues would be reduced ready for the refiner.

The Chairman said he was afraid that this system was not suited to the means of every photographer. He had been asked for a simple and efficient way to reduce residues. He counselled amateurs and others to dilute the residues with a large quantity of water, acidulate it with a little hydrochloric acid, and throw in a few scraps of zinc.

I informed the Chairman that I had formerly employed that system, but was obliged to abandon it, as I found that all the silver bromide was not reduced, because the nascent hydrogen very rapidly reduced the silver bromide in juxtaposition, and then the action was stopped in a great measure. Instead of sending metallic silver to the refiners a great part of it was unreduced bromide of silver, which was found to be a sheer loss. I found the best plan was to dissolve out of the gelatine films, emulsions, and plates all the silver iodides and bromides by hyposulphite of soda. When the hypo. solution is saturated the silver is precipitated by a solution of pentasulphide of potassium. By this system I can obtain a better result than by any other method.

M. Bardy exhibited a very fine microscope made by M. Duboscq. This instrument can be converted into a camera for photomicrographic pictures with the greatest ease. A conical tube is placed upon the top over the eyepiece, bearing not a ground glass but a very finely-polished one, divided into squares by diamond cuts. When the object has been finely focussed and the chemical focus of the lens (if any) allowed for, the glass is taken out and replaced by a dark slide containing the sensitive surface.

M. Vidal made a communication on ceramic productions. He regretted that photography was not sufficiently employed in the decoration of chinaware, and exhibited coloured proofs such as are used at Limoges. These prints are upon gummed paper, and resemble those coloured pictures which so amuse children and are known by the name of "*décalcomanie*," the only difference being that the colours used in the pictures for decorating chinaware, &c., are chosen to stand heat, and are composed of metallic oxides. The picture and its colouration is generally far from being a work of art, and M. Vidal is of opinion that if these "would-be artists" could be persuaded to employ photography the work done would be much more correct and render service to public instruction.

M. Vidal has experimented upon the best system to attain the object in view, namely, making enamel portraiture, &c., and that mechanically. He proposes to modify Mr. Woodbury's process in this wise:—Instead of gelatine being employed to hold the coloured matter, M. Vidal proposes the use of gum. A metallic oxide is mixed in a thick solution of gum arabic, and poured upon the leaden proof of a Woodbury press. The paper is put on and the lever is pulled down. Now, we all know what happens when gelatine is used. The gelatine sets, adheres to the paper, and when the press is opened an image is raised, showing all the form of the leaden model. Now gum will not set, but will remain liquid. M. Vidal has overcome this difficulty by coagulating the gum with rectified alcohol. After having placed the paper upon the coloured gum the press is closed, and thus all the excess of colour is driven out. The press is then lifted, blotting-paper impregnated with absolute or pure alcohol is now laid upon the paper, and the press is again closed. The alcohol goes through the paper, and sets or coagulates the gum. In a short time the paper bearing the image can be raised and transferred to the enamel, and then burnt in. This system would be much more rapid than the dusting-on process. It remains to be proved whether it be practical on a large scale.

A new invention, or "photographic colours," was then discussed. I can do no better than quote the paragraph from *The Times* of May 2nd last:—"*Photographing Colours.*—An engraver at Versailles claims to have discovered the art of taking photographs in colours; or, in other words, of reproducing the colours of the body or landscape photographed." This is, as usual, a *canard*, as well as a secret process.

An engraver of Versailles, named Baudran, has been soliciting the Ministre de l'Instruction Publique for a yearly subvention or grant of money, in exchange for which he would reveal a secret by which all the pictures in the Louvre could be reproduced in natural colours. So insinuating was he and so firm in his own belief that he succeeded in imparting some of his own confidence to many government officials. An appointment was made, and the inventor was asked to reproduce a picture. Of the number of the picture he had been previously informed. On the appointed day he made an experiment before the Ministre de l'Instruction Publique and a great number of statesmen. The preparation was covered with black paper, as he said he could not divulge his secret, &c., &c.; in fact, his manner appeared like that of Robert Houdin, or any other conjuror or wizard. In a drawer he tore off the black paper from his preparation, put the latter into a printing-press upon the negative of the picture, and exposed it to the sun's light. The exposure being sufficient the preparation was taken out of the printing-frame, plunged into a bath, when, lo! and behold! a very pretty reproduction of the picture was presented to the audience with all the colours of the original. "Marvellous!" "Wonderful!!" "Extraordinary!!!" and many other such expressions were heard and repeated. At last, when the enthusiasm had subsided a little lower than boiling-point, one of the audience—another St. Thomas, if not so incredulous as the saint in question—was at least wise enough to insinuate that before the world should be informed of an invention far above any of the nineteenth century, and which would not only confer honour and riches upon the inventor but shed glory upon France, &c., &c., it would be wise to have the opinion of some practical men well versed in photographic manipulations, &c. The proposition was seconded, and the inventor was politely informed that another interview would be accorded to him. A council of scientific men was called, and the following is, within a little, the result of their investigations:—That the inventor has not succeeded in reproducing natural colours by photography. This is short and explicit.

I will now endeavour to inform my readers how the inventor deceived himself, and how the results he obtained can be got by any amateur or photographer. M. Baudrau is an engraver and an amateur photographer, but not very conversant with photographic lore nor manipulations. This may be his excuse. Now, let any person take a negative of a picture, print the image very slightly upon salted paper—that is to say, paper prepared with a chloride and then sensitised upon a silver nitrate bath. Upon this skeleton of an image must be painted the colours of the original picture, and that as similar as possible. The colours to be used must be those mixed with albumen. I believe such colours are sold in England under the name of "moist colours." When the colouring is completed the paper is floated upon a solution of albumen salted with a chloride. When dry the paper, canvas, or other material is sensitised upon a silver nitrate bath, and when dry it is placed in juxtaposition upon the negative. The photographic image is now fully printed out, as in an ordinary silver print. The image is then plunged into a solution of hyposulphite of soda, and when fixed it is well washed and then dried. All the colours can be seen through the albumen, the photographic image giving the half-tones and shades—in all presenting a very pretty appearance, and quite capable of inducing any one to cry out "wonderful!" This is the history of photography in natural colours which has made so much noise—not only in scientific circles, but also among the public—during the last few days.

The Secretary mentioned the loss which photography had sustained in the death of J. B. Dumas, one of the most illustrious representatives of modern chemistry, and a lover and energetic protector of photography. Perhaps had it not been for the pecuniary aid he gave to Daguerre, photography or the development of the latent image would still remain to be invented. France has to weep for one of her *savants.*

England has to bewail the loss of one of her children in the person of the amiable President of the South London Photographic Society. I had unhappily only the pleasure to be in his company once or twice, and I sincerely sympathise with the Society in their loss, and bewail with the family in their sad bereavement.

A new publisher of photographic publications has come to the front in the person of M. Tiquol, 45, Quai des Grands Augustins. He has just published a work by M. Liebert, the well-known photographer, on carbon printing, being a practical description of the process and its manipulations. I wish success to the author and publisher.

25, *Rue des Apennins, Paris, May* 5, 1884. E. STEBBING, *Prof.*

INCREASING THE RAPIDITY OF COLLODION EMULSION FILMS.

To the EDITORS.

GENTLEMEN,—It has often been desired—at least by those who used formerly to practice the old collodio-bromide process—to obtain quicker results on plates thus prepared. Reading in last week's Journal Mr. W. K. Burton's article on mixing emulsions and your leader on the same subject, it occurred to me that something might be done towards increasing the rapidity of collodion emulsions.

You will recollect that last year Mr. E. Banks wrote some very able and interesting articles on collodion unwashed emulsions, in which one of the main features of the process he recommended was the small amount of pyroxyline used in the collodion. The plates having been coated with collodion emulsion were washed and then coated with gelatine, which allowed a strong developer to be used without fear of fog. I for one followed those articles, and experimented in that direction with a certain amount of success; and I have reason to hope that that success will be carried still further by adopting the principle contained in the articles referred to above as to mixing emulsions.

My proposition is to carry out Mr. Banks's process up to the point where he coats the collodio-bromide plate with gelatine; but, instead of gelatine, to use a thin, rapid gelatine emulsion just floated over the plate and run off at the corner, so as to leave a very slight trace of gelatino-bromide over the collodio-bromide. This would act as an accelerator and preservative, and would develope quickly, which development would be communicated to the collodio-bromide film in much the same way as by first setting fire to a few sticks, coal will take fire from them.

This, if successful, will bring our old friend once more to the front as an old friend with a new face, and I trust with a sparkle on his face, too; and I am sure the process would be welcomed by many old workers.

Plates thus prepared would dry very quickly, and could be used wet, if desired, in the studio or out of doors; and for coating large plates, which are sometimes very uneven, it would possess an advantage over gelatine, which requires levelling. They would also be more uniform and more easily worked in hot climates, and the films could readily be transferred or detached.

During the next few days I hope to put this process to a trial, and I hope other old workers will do the same, as I feel sure there is something in it.—I am, yours, &c., G. V. J. POIRON.

8, *Victoria-chambers, Westminster, May* 6, 1884.

DARK-ROOM ILLUMINATION.

To the EDITORS.

GENTLEMEN,—It is satisfactory to hear from Mr. A. Pringle that the committee of which he, Mr. J. M. Turnbull, Mr. J. G. Tunny, Mr. Hume, Mr. Jamieson, Mr. W. Forgan, and other gentlemen were members, found, as the result of their experiments, that a yellowish-green light had the least effect upon a sensitive plate when compared with a ruby light; but it is disappointing to be informed that, in spite of this, Mr. Pringle himself prefers ruby light, because to him yellow green is obnoxious.

I venture to say that a prefence for red light, as a matter of comfort and pleasantness to the eyes, is quite exceptional; and, although it is desirable to put exceptions on record, it would be of general service to know the views of the other gentlemen who took part in the experiments.—I am, yours, &c.,

London, May 6, 1884. W. E. DEBENHAM.

STANDARD DIAPHRAGMS.

To the EDITORS.

GENTLEMEN,—As we have numerous inquiries as to whether it is our intention to adopt the standard diaphragms recently recommended by the Photographic Society of Great Britain, permit us to state that we have already done so for some time in our new formulæ of portable and rapid symmetricals, and have advertised this fact in the ALMANAC for the present year.—We are, yours, &c., ROSS AND CO.

112, *New Bond-street, London, May* 7, 1884.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—Please allow me space for a few lines to inform intending contributors to the "Statham Testimonial Fund" that the subscription list will be closed tomorrow (Saturday), May 10th, and oblige,—Yours, &c., F. A. BRIDGE,

9, *Norfolk-road, Dalston-lane, E., May* 9, 1884. *Hon. Sec. and Treasurer.*

A CORRECTION.

To the EDITORS.

GENTLEMEN,—Permit us to correct an error in the report of the Liverpool Amateur Photographic Association with respect to the new stand shown to the members by Mr. Cornish.

The stand was first introduced and is manufactured by us. We are not merely the agents for its sale, as incorrectly stated in the report.—We are, yours, &c., NEWTON AND CO.

5, *South John-street, Liverpool, May* 5, 1884.

Notes and Queries.

SYNTAX inquires:—"Of the following two methods of intensifying a gelatine negative—*a*, bichloride of mercury, followed by ammonia; *b*, bichloride, iodide, and hyposulphite, as recommended by Edwards—which is to be preferred?" —— In reply: The former is believed to be the more stable.

"I have a plano-convex lens twelve inches in diameter which I wish to mount as a condenser for solar camera purposes. Which side should I place next to the negative?—FRED. B. HASLETINE."——In reply: The flat side must be next the negative, the convex surface being to the outside.

C. WALKER inquires:—"Can you tell me why the photographic image appears upside down on the ground glass of the camera? A friend of mine is very anxious to know why it is not correct, the same as shown in an opera glass; and because I am in the photographic profession he taunts me about not being able to explain the reason."——In reply: It is somewhat surprising that our correspondent allows himself to remain in a state of ignorance on such a simple matter, when by reading the literature of his profession he may so easily acquire knowledge. Meantime we refer him to that chapter in the series of articles on the *Optics of Photography and Photographic Lenses*, published in our volume for last year, entitled "The Cause of an Inverted Image," to be found on page 276. After reading this he will experience no difficulty in giving a reply to his friend.

"Is there any advantage in fuming ready-sensitised paper, or should it be used just as purchased?—A. SCOTT."——In reply: There are some brands of paper which will not yield good tones unless they are very much fumed; but, as a rule, paper purchased from respectable dealers is ready for placing in the printing-frame without such preliminary treatment. Fuming may be resorted to if there be much difficulty experienced in getting a good tone.

H. T. asks:—"Is it necessary, when making chloride of gold from coins which have been alloyed with copper, to remove the baser metal; that is to say, will the presence of the copper in the finished chloride have an injurious action on the tones of the finished prints?"——In reply: Chloride and nitrate of copper have a certain toning action which is said to pass away in the fixing-bath; but we have not heard of any injurious effect having been produced by their presence in the chloride of gold. Perhaps some reader who has had experience in this direction will give some information.

F. B. J. writes:—"I have occasionally heard of dark slides for gelatine negatives which have been formed throughout of paper or thin cardboard. Is this possible? and, if so, where can such slides be obtained?"——In reply: It is quite correct that dark slides of this class are made and sold—but only in America, not in England. It is said that they answer the intended purpose exceedingly well, their thickness being such that twelve slides filled with plates only equal in bulk eighteen plates when piled together. The camera must have a special adapter made for these slides. We are unacquainted with the details of their construction, but imagine that they will not be able to stand much wear and tear.

G. M. D. inquires:—"Can you inform me what are the advantages claimed to accrue from fuming sensitised silver paper with ammonia? I read in certain American works accounts of the method of printing, and ammonia fuming forms in every case an integral portion of the operation; whereas, on the other hand, I cannot discover any recommendation of, or even allusion to, it in several English works which, from the status of their authors, should be considered authoritative."——In reply: The advantages alleged to be derived from fuming with ammonia are increased sensitiveness, the possibility of obtaining good tones with a weaker silver bath than usual, and a rich tone with a minimum of gold. It is better to make use of strong ammonia and short fuming than to fume a long time with weak ammonia.

J. T. T. says:—"With reference to the adaptation of a Nicol prism to a lens for obtaining landscapes: there is no doubt that from the very nature of its construction very few other than central rays can be transmitted so as to prove of any benefit in depolarising the light from a landscape. Having a large Nicol prism capable of transmitting a beam of light, large in a corresponding degree, I had it fitted to the lens of a pantoscopic camera; and, as the rays by which the plate in this camera is impressed are all axial, I have had complete depolarisation of a subject measuring 120° on the base line of the picture. I do not attach much importance to this feat, as there are only few circumstances or occasions under which it will be of practical value; still, it is well to place it on record as a means—and, so far as I can see, the only means—by which the photographing of a wide angle of view by the agency of depolarised light can be effected."

"AT the lecture on photographic composition, delivered by Mr. Norman Macbeth at the recent meeting of the South London Photographic Society, it was stated that Burnett's treatise on *Composition* was out of print. Considering how highly it was eulogised by the lecturer permit me to inquire if it could not be reprinted? There is now no copyright restriction applicable to this case, as the author has been dead for a very long period—indeed, over the seven years mentioned in the act.—X. Y. Z."——In reply: The work mentioned, although valuable to painters, is not so to so large an extent to photographers. We believe it was reproduced by photolithography (for there are more pictures than letterpress) in America some years ago; but, so far as we are informed, it was not appreciated by photographers as highly as might have been considered desirable. Such a discourse as that by Mr. Macbeth, prepared as it was specially for photographers, if published *in extenso* and illustrated by the various diagrams and pictures he exhibited, would prove invaluable to every one who makes use of a camera for taking either a landscape or a portrait.

POSTMASTER writes:—"I am glad to see the subject of lenses of long focus mentioned by 'R. F. W.' When I read his letter I unscrewed the lens of my astronomical telescope, which is rather larger and of longer focus than that of your correspondent. I fixed it temporarily in a hole in an extemporised shutter adapted for a small window in the rear of my house, but from which a fine view is obtained. As might have been expected, I was charmed with the large and distinct view projected on a sheet of white cardboard upon which I received the focus. But I reasoned in this way: the only difference between this image and one obtained from the same point of view by any other, even the smallest, lens is one of actual magnitude, not of difference in proportion. Why, therefore, not employ a quarter-plate camera to obtain a negative, and enlarge this up to the same dimensions as those yielded by the large and costly object-glass? Not much sooner said than done. As the quickest way of proceeding I exposed a bromised collodion plate, developed it by alkaline pyrogallol, treated it with nitric acid, placed the transparency thus obtained in an oil optical lantern, and projected its image side by side with the direct large one obtained by the costly telescopic objective. Both were alike in dimensions. What conclusions ought I to draw from this experiment?"——In reply: The inference to be deduced from the experiment narrated is that a well-made enlargement is of equal value with a direct large picture—a doctrine that has been invariably taught in this Journal for many years.

Exchange Column.

No charge is made for inserting these announcements; but in no case do we insert any article merely OFFERED FOR SALE, *that being done at a small cost in our advertising pages. This portion of our columns is devoted to exchanges only. It is imperative that the name of the person proposing the exchange be given (although not necessarily for publication, if a* NOM DE PLUME *be thought desirable), otherwise the notice will not appear.*

I will exchange two boxes ferrotype plates, 14 × 10, 200 in box. Wanted, good half-plate lens, or offers.—Address, STUDIO, Frederick-st., Cardiff.

I will exchange roller background frame, to carry six or more changes, for good 10 × 8 field camera, or offers.—Address, H. G., 158, Regent-street, W.

Wanted, Dallmeyer's rapid rectilinear or Ross's rapid symmetrical lens, in exchange for Dallmeyer's 4D patent lens.—Address, SMALLEY BROS., 2, West-street, Fleetwood.

I will exchange a 10 × 8 wide-angle view lens, Photo. Stores make, new; what offers? Wanted, Solomon's magnesium lamp.—Address, TAYLOR, photographer, Chislehurst.

I will exchange a Victoria camera, with four lenses, and part cash, for a 10 × 8 or 12 × 10 patent group lens by a good maker.—Address, W. S., 13, Trinity-street, Hanley, Staffordshire.

I will exchange a good dark tent, Murray and Heath's, very compact, suitable for a dark room, for a half-plate camera with double slide, or offers.—Address, R. MORRIS, 97, Price-street, Birkenhead.

I will exchange a Solomon's magnesium lamp, double burner, with two coils of ribbon, cost £4 10s., for a good magic lantern.—Address, A. PARKER, photographer, Broughton-in-Furness, Lancashire.

I will exchange a photomicrographic camera, 36 inches bellows focus, for a good half-plate or whole-plate lens, by a good maker; also, THE BRITISH JOURNAL OF PHOTOGRAPHY for 1873 for anything useful.—Address, C. G., 31, Wigan-street, Bradford, Yorks.

I will exchange a portable half-plate tourist bellows-body camera, three double backs, and frames for other sizes, with tripod and view lens, for a whole-plate bellows-body camera and double back.—Address, GEORGE T. HARRIS, Long-street, Atherstone, Warwick.

What offers in exchange for a 10 × 8 ebonite bath and dippers, with cover, a 12 × 10 porcelain ditto, collodion filter, Thomas's tent, with wheels, Solomon's cabinet hot press, and Vogel's whole-plate triplet lens?—Address, A. GOULD, Glen View Studio, Bournemouth.

I will exchange a 12 × 10 portable Kinnear camera, with one dark slide, in good order, Watson's twenty-one shilling shutter, new, a drop shutter, fits two sizes of lenses. Wanted, Solomon's enlarging lantern and a large-sized doublet lens, or open to offers.—Address, T. L. W., 19, Beckenham-road, Penge.

I will exchange a biunial lantern, four inches condensers, about 150 slides, gas bag, boards, retort, screen, frame, &c., together or separate; also, light, four-wheel waggon for the above, suitable for a boy to draw. What offers in good photographic apparatus?—Address, 283, Broadfield-terrace, Abbeydale-road, Sheffield.

Wanted, a No. 3 Ross's portable symmetrical lens, must be in perfect condition, in exchange for any of the following:—A Seavey's rustic stile and steps, cost £4 10s. (equal to new), an Oakley's A1 tripod, two good head-rests, by Harrison, and two cameo, cabinet, and *carte* embossing presses, by Marion, also a superior iron studio table, with walnut circular top and inlaid chessboard. Photographs and particulars of any of the above on application.—Address, EDWIN ECCLES, 15, Broad-street, Bury, Lancashire.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

NOTICE.—*Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a* NOM DE PLUME *as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.*

ALEX. SCOTT.—Doubtless one of the zinc etching processes was referred to by the lecturer.

PHOTO.—Dickens's *Dictionary of London*, price one shilling, will answer your purpose best.

ARGOL.—The paper may be obtained direct from the Willesden Paper Company. Their address is Willesden, Middlesex.

B. P.—Any good portrait lens having a back focus of six inches for *cartes* and eight inches for cabinets will answer. The latter will suit both purposes.

BROMO.—Precipitate the iron, either with caustic or carbonate of potash, and employ the solution for making a new developer by the addition of fresh iron.

A NOVICE.—The addition of a small quantity of carbolic acid to starch paste, if employed for mounting photographs, will exert no injurious effect upon the pictures.

F. E.—This correspondent directs our attention to an advertisement in our last number. Had the advertisement alluded to come under the notice of the Publisher of this Journal it would not have been inserted.

J. C.—The plate will keep best if preserved in the same packages in which they are issued by the manufacturers. The method of keeping proposed by yourself would be no improvement.

R. W. C.—In reply to your query, we must ask what you consider the requirements of "a professional landscape photographer," what process he is to work, and what size of picture he is to take?

G. T. H.—1. Yes, if the light be good and the plates very sensitive; but not otherwise.—2. If you send the pictures here, together with postal orders for one shilling and sixpence for each picture, we will effect the registration of copyright for you.

Wm. Prentice.—No wonder the plates fogged if your window was "protected" with the fabric of which you send a sample. In reality it is no protection at all. It admits a large proportion of the violet ray. It is quite useless for dark-room windows.

Thos. Snowdon.—1. If the wax be not decomposed the spots can doubtless be removed by subjecting the picture to a moderate amount of heat.—2. We are not aware what kind of mountant the gentleman employs. Probably glue applied to the edges only of the picture will answer quite well.

E. Jacobs.—As the lenses are sold for a few shillings each, and have the same number of glasses as a portrait combination—which, indeed, they are in miniature—you cannot expect them to possess a very high degree of perfection. Certainly they cannot be expected to answer for photomicrography.

Hugh.—We cannot, at a moment's notice, search out the particular number of the Journal in which the process was first published. Dr. Eder says the plates will keep six days, and probably longer. Opticians in their catalogues, as a rule, mention the back focus of their lenses, and not the equivalent focus.

A. G. Downing.—1. No satisfactory method. You had better make a negative and produce the prints from that.—2. We cannot in this column devote the space necessary to give the working details of an entire process, more particularly when the process has been an obsolete one for many years, and is, therefore, of no interest whatever to our other readers.

R. J. B.—The portraits are by no means well produced. Their principal fault lies in the lighting. Too much front light has been used; hence the pictures are flat and lacking in rotundity. Stop off a large proportion of the light in front of the sitter, and admit a stronger one at the side. If by this treatment you find the shadows are a little too heavy, soften them by means of the reflecting screen. There is no fault whatever in the construction of the studio—rest assured of that.

R. A.—Employ a small stop in the lens, and use a very large proportion of restrainer in the development.—2. Gelatino-chloride plates will not be suitable for the purpose.—3. Dry collodion would possibly answer best; but plates by this process can scarcely be considered an article of commerce nowadays. With slow gelatine plates, and a developer well restrained, you should experience no difficulty. The notice with regard to correspondents enclosing name and address does not appear every week. It appeared the week you wrote, and again this week.

G. Richards.—This correspondent asks—"How long will sensitised carbon tissue keep good?" This is a difficult question to answer, inasmuch as all will depend upon how it is dried and how it is kept afterwards. If the tissue have occupied a long time in drying it will not keep long—probably not more than a day or two. If it be quickly dried, and then carefully preserved from atmospheric influences, it will keep good for two or three weeks. We have kept some for as long a period as six weeks after sensitising; but this was an exceptionally long time. You can certainly "purify" the bichromate of potash by recrystallising it; but this it is scarcely necessary to do if you get a good commercial sample. The addition of a small quantity of spirit of wine will not cause a precipitation of the salt.

A Miniature and Portrait Painter writes:—"Can you tell me what is the best plan to adopt with regard to photographers who carry on the following system:—They send a small order accompanied by cash; this is followed by a larger order, which they pay for; and then comes a still larger order, which they *don't* pay for. They obtain the artist's confidence, and then abuse it. I believe there are several men who carry this plan on regularly with all the advertisers. Four photographers have treated me like this lately. They expressed themselves perfectly satisfied with the work, promising cash by next post; but since then I can get no reply to any application. Can such men be shown up?" We hope our correspondent will take legal proceedings, and thus "show up" at least one of the fellows who follow such nefarious practices.

Photographic Club.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 14th inst., the subject for discussion will be—*On Developing with and without Sulphite of Soda.*

An Outside Recognition of Photography.—At a *conversazione* in connection with the recent Exhibition of the Horticultural Society of Liege, Belgium, an album of Mr. Henry Stevens' flower studies, which happened to be in the possession of the President of the Liege Section of the Belgian Photographic Association, was exhibited by him, and so pleased the horticulturists that the Society has done Mr. Stevens the unsolicited honour of awarding him a *medaille en vermeil* for the excellence of his photographs. The Belgian Photographic Association has also awarded him a special diploma in addition to the medal gained at the recent exhibition.

Photographic Society of Great Britain.—The next ordinary meeting of this Society will take place on Tuesday next, the 13th inst., at eight p.m., at 5A, Pall Mall East (the summer exhibition of the Royal Society of Painters in Water Colours being on view), when the following papers will be read:—*Observations on Fading*, by John Spiller, F.C.S.; *Illumination of the Dark Room*, by W. E. Debenham; and *Commercial Fabrics Suitable for Dark-Room Illumination*, by J. R. Sawyer.

The Photographic Artists' Co-Operative Supply Association, Limited.—*On dit* that the business of this Company, carried on at 43, Charterhouse-square, E.C., has changed hands, and that a new Company has been formed to carry on the concern on the co-operative principle. Mr. A. H. Loring, Mr. A. F. Charrington, and Mr. W. B. Whittingham are mentioned as being on the Board of Directors, and Mr. H. R. Faulkner, who has been connected with the concern for upwards of five years, has been appointed Manager and Secretary.

Business Changes.—When recently visiting the establishment of Messrs. Horne and Thornthwaite, philosophical and photographic instrument-makers and dealers, Strand, we were not a little gratified to find that the business had passed by purchase into the hands of our whilom contributor, Mr. James Martin, who will be remembered as having been for many years connected with the business while it was conducted in Newgate-street. Mr. Martin has made the purchase on behalf of his son, who has graduated in a good school, no fewer than eight years of the time devoted to acquiring a knowledge of the routine of the trade having been passed in the establishment of Messrs. Ross and Co. Aided by the great photographic experience of Mr. Wm. Ackland—who still controls the important spectacle department—we have no doubt that Mr. Martin, Jun, will prove thoroughly successful in carrying on and increasing the business of Messrs Horne and Thornthwaite, the familiar title of which firm is still continued under the new *régime*.

The Law of Copyright.—Mr. Hastings has again introduced a Bill to amend and consolidate the law of copyright in works of fine arts and in photographs, and the Bill was read a first time in the House of Commons on Wednesday. The Bill is backed by Mr. Hanbury Tracy, Sir Gabriel Goldney, Mr. Agnew, and Mr. Gregory, as well as by Mr. Hastings. It is, we understand, substantially the same Bill as that introduced last session, but it has been carefully revised, and some modifications and additions have been made with respect to copyright in photographs, to meet, or rather avoid, the vexed question, "Who is the author of a photograph?"—a question that puzzled the learned judges in the case of Nottage *v.* Jackson, in which the ownership of copyright in a photograph of the Australian cricketers was in dispute. A short Bill intended to meet this point, and this point alone, was introduced towards the end of last session by Mr. McLaren, but was dropped at an early stage. When the present Bill is printed we propose to examine and comment upon the clauses dealing with photography.—*Athenæum.*

METEOROLOGICAL REPORT.

Observations taken at 406, Strand, by J. H. Steward, Optician,
For three Weeks ending May 7, 1884.
These Observations are Taken at 8.30 a.m.

No. 1254. Vol. XXXI.—MAY 16, 1884.

IODIDE OF SILVER IN EMULSION.

At the close of our article on this subject last week we reiterated the opinion we long ago expressed that the presence of a certain proportion of iodide of silver is not necessarily injurious to the sensitiveness of an emulsion of silver bromide. We say "not necessarily" because under certain conditions such an addition will, undoubtedly, lower the degree of sensitiveness in the same manner that other substances will do.

Thus, if an emulsion be boiled or stewed in the neutral state for a given period, a certain degree of rapidity will be attained; but if to a second quantity, otherwise similarly treated, a small trace of acid be added, an equal degree of sensitiveness can only be gained by more prolonged cooking. In like manner the presence of a small quantity of iodide of silver lengthens slightly the period of cooking necessary to produce a given degree of rapidity, and this in proportion to the quantity present; but, so far as we have been able to ascertain, if the proportion of iodide be kept within reasonable bounds, there is no permanent injury done to the sensitiveness of the preparation, its only slowing effect being manifested in the operation of cooking.

But, setting aside for a moment the question of sensitiveness, the presence of iodide of silver, it is almost universally agreed, confers beneficial effects upon an emulsion. The chief of these is the opacity it gives to the film, which minimises the chance of mechanical "halation" (by reflection from the back surface of the glass), and its specific action in the film itself in preventing chemical halation by separating the particles of silver bromide, as pointed out by Captain Abney. It has also been claimed that the admixture of silver iodide renders necessary a less "safe" light in the developing room; but it has never yet been satisfactorily proved whether this is actually the case—so far, at least, as it was said to reduce the sensitiveness of the film to rays of lower refrangibility.

That films containing iodide are less liable to fog, are more easily managed, and give generally clearer and brighter negatives under similar conditions than those of plain bromide, is a fact which no one who has used both kinds can have failed to notice; and the difference in this respect is the more palpable in proportion as the sensitiveness of the preparations is increased. Indeed, in the course of a discussion on the subject of plates combining exalted sensitiveness with perfection of quality, a well-known emulsion maker some months ago expressed to us the decided opinion that in order to secure this much-to-be-desired combination of qualities a certain proportion of iodide is *absolutely necessary*.

It is possible that this extra cleanness and vigour in working which an iodide plate displays when compared with a plain bromide one, while being purely chemical in its character, may have given rise to the supposition alluded to that the sensitiveness of the film to certain rays is lowered. In other words, if two plates of equal camera-sensitiveness—the one a plain bromide, the other a bromo-iodide—be developed side by side under identical conditions of light, and the one fogs while the other does not, then, assuming that in the case of the bromide plate the fog is caused by excess of light or by light of an unsuitable character, it would be only reasonable to argue that the bromo-iodide plate, while equally sensitive in the camera, is less easily affected by light of a certain colour which suffices to fog plain bromide.

But if the cause of the fogging action on the bromide plate be not light, but merely a stronger tendency to abnormal reduction under the action of the developer, then that argument fails completely. If instead of "light" fog it be really "chemical" fog, then it only proves that iodide has a beneficial chemical action wholly independent of any consideration of the quality or quantity of the light admissible during the various operations of preparation and development.

The following experiments, from amongst many, will illustrate our meaning and tend to show that any advantage which iodide confers upon the film is entirely beside the question of its colour sensitiveness:—Two plates of commercial manufacture, and as nearly as possible equal in sensitiveness (the one plain bromide, the other bromo-iodide), were exposed and developed side by side in separate dishes until each exhibited the same amount of detail in certain portions of the subject. Both plates were equally exposed to the light (ruby and orange) during the time of development, and, upon fixing, the plain bromide plate showed a decided veil while the other was quite clear.

Two similar plates were exposed and developed, the dishes this time being kept covered, so that practically the development was effected in the dark. Upon fixing, the bromide plate was again found to be veiled, being, in that respect, not a whit better than the one which had been freely exposed during development. Here we had ample proof that the difference was not caused by light but by the necessity, on the part of the bromide plate, for a more powerful fog restrainer.

Another line of experiment was then taken. The quantity of restraining bromide necessary to retain the clearness of the bromide plate during the application, for a measured time, of a developer of the strength already used having been ascertained, two more plates were exposed, as before, for equal periods, and afterwards developed under identical conditions. In this case, however, though the bromide plate came out without veil, it was most decidedly less exposed than the other. Here, then, we find that iodide of silver is capable of replacing soluble bromide as a fog restrainer, and, what is of greater importance, it performs that function with less effect upon sensitiveness of the plate than is exercised by the bromide; consequently, there is a probability we may be able to prove that, *cæteris paribus*, a bromo-iodide plate may be actually *more* (instead of less) sensitive than a plain bromide one.

In a subsequent article we shall show that iodide is capable of perfectly replacing free acid during the preparation of the emulsion, and is especially valuable in connection with the ammonia methods.

PHOTOGRAPHS ON IVORINE: A NOVELTY.

It is scarcely necessary to make any explanation as to what is meant by "ivorine," seeing that it has been so extensively used during the last year or two in the production of Christmas and birthday cards, and is, therefore, familiar to everyone. The surface of this material, from its ivory-like texture, is exceedingly easy to paint upon, and very delicate and effective pictures can be produced with the expenditure of but little time or skill, and, consequently, at a very cheap rate.

Ivorine, it may be explained, is simply gelatine containing some white pigment, such as sulphate of baryta or oxide of zinc, together with a small proportion of glycerine, to prevent its becoming brittle when in thin sheets. This solution (or, rather, emulsion) is poured upon a levelled glass plate, allowed to set, and the plate is then reared up to dry in the same manner as ordinary gelatine plates. When the coating is dry, the film is stripped from the glass, and this is the ivorine of commerce. It is almost needless to say that the glass must have previously been waxed or rubbed over with powdered talc to prevent the film from adhering when dry.

When looking over a number of these effective little pictures on ivorine it occurred to us that photographs on the same material would be exceedingly effective and very convenient for the album, as they would be thinner than prints on the ordinary mounts. Also, from the translucent character of the ivorine, the pictures could be viewed as transparencies—a double advantage. Furthermore: there would be a certain amount of novelty about such pictures which would possibly render them a success if introduced commercially. The idea of employing artificial ivory is by no means new, as from the very early days of our art-science it has been used—or, perhaps, it would be more correct to say has been attempted to be used, as the results produced were not always the most successful. However, the late Mr. Burgess, of Norwich, did undoubtedly produce—and on a commercial scale, too—some most charming pictures by what he named the "eburneum process."

Mr. Burgess's plan was to produce a collodion picture on glass in the camera, as in the collodion transfer process, and then to apply the eburneum mixture in a fluid state. This, in composition, was similar to that now used for the manufacture of ivorine, except that it contained a larger proportion of pigment. Although the eburneum process was very successfully worked by Mr. Burgess himself, it was not to any extent employed by others, as it involved some few difficulties which they did not appear to surmount. The chief of these were that by camera printing it is difficult to obtain pictures of a pleasing, warm tone, and the inky-black, so generally obtained by this method, was very objectionable on a material like ivory. Added to this, the gelatinous coating, on account of its thickness, took a very long time to dry, several days being frequently necessary in damp weather.

We know quite well that any process to be useful commercially must not be beset with difficulties, as was undoubtedly that just alluded to; hence we abandoned the idea of employing the gelatinous preparation in a fluid condition. Having ascertained that ivorine is an article of commerce, and is sold by most fancy stationers, we procured several samples, and found, as might be expected, that when placed in cold water they became soft and pliable like ordinary gelatine. In hot water, after soaking in cold, they dissolved freely, though some more so than others—possibly from the more insoluble ones containing a certain proportion of alum. From these experiments it was clear that ivorine could be made to take the place of paper, either in the collodion transfer or the carbon process.

In putting the idea into practice with the latter process we met with no difficulty whatever, and here is the method we adopted:—Some carbon prints were made upon collodionised glass, in the same manner as if they were to be transferred to paper, except that they were not allowed to dry after being "alumed." The ivorine was then soaked in water until it became quite limp. It was now removed and laid upon the picture, the superfluous water being expelled with a very soft squeegee. The pictures were then allowed to dry, when they were stripped from the glass and trimmed round the edges with a pair of scissors. The pictures, it may be mentioned, were developed and the ivorine applied in the evening, and they were found to be perfectly dry by the following morning. Nothing can be simpler to work than this process, and the results produced are exceedingly pleasing. One or two things noticed during the experiments may, however, be mentioned, as they may be of some little assistance to those who may try the process. The ivorine must be made thoroughly and evenly soft, otherwise, when it is squeegeed on to the glass, it will "buckle up" and leave the picture. This we noticed particularly with one of our pieces which happened to be thicker at one end than at the other. When this piece was applied to the glass the thickest end (although quite soft, was not so soft as the other) could not be kept down, but upon re-soaking it all difficulty disappeared.

It is advisable not to soak the ivorine more than is necessary, as the longer it is soaked the longer it will, of course, take to dry. All the moisture it is possible to expel with the squeegee should be expelled; for, if any superfluous water be allowed to remain on the surface, it will cause the gelatine to continue swelling, and be liable to produce markings on the back of the finished picture from unequal drying.

In our first experiments we had some doubts as to whether, if the ivorine were simply softened in cold water, it would prove sufficiently adhesive to the carbon film; but our doubts were groundless, as by no possible means could the two films be separated when dry. However, it is quite possible that some samples of ivorine may be more insoluble than those we tried, and the mere treatment with cold water will not be sufficient. We therefore placed a sheet of it in tepid water before applying it to the picture; but this rendered it very difficult to manage, as the heat dissolved, or partially dissolved, both surfaces.

We then hit upon the following plan of softening, or, rather, bringing about a state of partial solubility of one side only, which at once overcame all difficulty:—The picture, after development and being treated with alum, was dried. A piece of the ivorine was now softened in cold water. The picture was placed in warm water, of about 110° Fahr., until the glass had acquired that temperature. The softened ivorine was then applied and squeegeed down as before. By this method of procedure only that surface in contact with the picture is partially dissolved, instead of both. When this plan is adopted the ivorine should be cut somewhat larger than the picture, as, when it is placed upon the warm glass, it appears to contract to a considerable extent. It is well to put a few American clips round the edges of the plate to prevent any portion of the picture from leaving it before all parts are dry, which might cause markings.

It may be as well to mention that brown tones, to our taste, are much preferable on ivorine to purple. Those most satisfactory, to our mind, were printed in a warm chocolate pigment; but, of course, this is merely a matter of taste.

We commend this process to those who are in search of novelties for the coming season as one that may prove remunerative.

PNEUMATIC AND HYDRAULIC SHUTTER APPLIANCES.

The eulogiums in which we indulged when giving, in 1878, the first details of the pneumatic shutter of Mr. J. W. T. Cadett have been well endorsed by the success with which it has been attended subsequent to that period. Ingenious experimentalists and mechanicians have had, by the invention of Mr. Cadett, their attention directed to the value of pneumatics in other directions than that described in the 1878 patent of this gentleman, mainly in that of discharging bolts or operating upon triggers, by which instantaneous shutters are started into action.

The convenience of being able to transmit through a long and tortuous piece of flexible and elastic tubing, by a touch at its farther extremity, the force by which the shutter is actuated is one sufficiently important to have induced photographers to ascertain, as far as possible, the full capabilities of the system, so as to note the direction in which further developments might be made.

When the flexible rubber tube is employed as the agent for insulating a pair of wires communicating with a tolerably constant battery of the capacity of three or four cubic inches, and without any liquid to spill, so as to be capable of being attached to an interior corner of a portable camera, with electric magnets *en suite*, then an exposing power of exceedingly great value will be placed at the services of photographers, who will very speedily discover the best and most convenient form in which to have that power applied.

We are quite well aware that, several years since, and by means of ingenious contrivances, electricity had been applied to cameras in the studio; but what we now aspire to has reference to those of a strictly portable class.

It is no secret that Mr. Léon Warnerke has recently obtained a patent for a method of transmitting force through a rubber tube, from the hand to the camera, by means directly mechanical rather than pneumatic. Having had an opportunity of examining the appliance we can speak of its success. The tubing, which need not exceed the thickness of the handle of an ordinary penholder, is lined throughout its interior with wire in close coils, such as that so commonly found in rubber tube employed for conveying gas—an addition which scarcely adds to the expense. Through the interior of this is passed, loosely, a second length of wire closely coiled, very much like the bass string of a pianoforte if the central core were removed, the action of the system resulting in this—that if a button at the end of the tube be pressed this pressure is immediately, and with almost full force, responded to at the further end by the interior tube or coil darting out with a measure of rapidity and force commensurate with that applied by the hand of the operator. Owing to the spiral form of the wire tubes it will readily be conceived that they may be curved or coiled without impairing the action of the central piece. As we shall have occasion subsequently to describe Mr. Warnerke's system in detail, no further allusion to it is at present necessary.

A system which was exhibited during the past week at one of the societies by Mr. A. Mackie elicited much attention from the exceedingly simple way by which pneumatic force may be rivalled by hydraulic force, in being made to operate upon an exposing shutter. It merely consists in filling the pressure ball and the connecting tube with water instead of air. That it answers the intended purpose there cannot be a doubt; and we are well aware that a patent, which was allowed to lapse two months ago, took cognisance of the substitution of water for air, strictly in this connection.

By way of experiment we have applied this hydraulic system to shutters of various forms which had been previously actuated by pneumatic force, and find that for some purposes—such as that of liberating a catch, pulling or pushing a trigger, or elevating a shutter or cap and keeping it so for a few seconds or minutes—the substitution of water for air is not attended with any disadvantage. Where it would prove less successful would be under circumstances in which two sharp puffs were required in rapid succession. This is, perhaps, not a likely contingency; but it is known that among the innumerable forms of quick-acting shutters is one, at least, which commences the exposure of the lens by one quick pressure of the pneumatic ball and terminates it by a second pressure, the sluggish action of water for such a purpose contrasting unfavourably with that of the more elastic atmospheric air. For every other purpose, however, the one fluid may be substituted for the other. It is possible that the thickness, and consequently the elastic power, of the rubber ball which acts as the reservoir for the force may have to be somewhat increased, and also that the water-ways of the fittings may have to be somewhat enlarged in order to secure the highest degree of efficiency. As stated, all our trials were made with appliances intended for air alone.

But another question here arises: how will the substitution of water or other non-compressible fluid for atmospheric air affect the original patent of Mr. Cadett? It is not pertinent to the question now before us to inquire here whether the claim for the shutter described and figured in that patent specification—which was republished at page 542 in our volume for 1878—be considered sufficiently comprehensive to include all that has since been effected—or, in other words, to include the broad principle of the application of pneumatics to the exposing of plates in the camera. This, we say, is a question which need not be discussed here; but what must prove of interest will be the ascertaining whether taking one, or a *facsimile* imitation thereof, of the admittedly-original patented pneumatic shutters, precisely as described in the clear language of the specification, and by ejecting the air contained therein and supplying its place with water, would be what in legal phraseology is designated a colourable imitation. And, if any case arising out of this were to be submitted to the Vice-Chancellor for adjudication, would he find that in this particular function air and water were considered in one and the same light, and that pneumatics and hydraulics were interchangeable terms?

If for the fluid in question oil, instead of water, were preferred, then further complications, especially in scientific nomenclature, would be expected to arise. On the other hand, should the discovery be made, as humorously suggested by a member at the meeting of the Society to which we have already referred, that the rubber ball may be made to enact the part of a flask for containing fluids for the refreshment of the inner man when fatigued with searching for and photographing the beautiful and pictorially-interesting scenes in nature, then we shudder in contemplating the dimensions at which this at present small, egg-shaped vessel may eventually arrive.

DROPPING, AND THE SIZES OF DROPS.

For many years, as it is scarcely necessary to remind our readers, we have seized every opportunity to express our sense of the necessity for exactitude in weighing and measuring in photographic operations, if any approach to uniformity of result be desired. It is gratifying to note that the old mode of describing these manipulations—such, for instance, as in the development of a dry plate, "a drop" of this and "a few drops" of the other—is comparatively rarely adopted nowadays. The manufacture of dry plates and, with it, dry-plate development, have made great strides towards perfection within a very short period; and, in consequence, to obtain the full value capable of being extracted from them, definite and accurate measurements must be not only made, but also described, in such a manner as to convey information to every hearer or reader.

Such information is not carried by the term "drop," and, whatever meaning the word may have for any one particular experimentalist, it is comparatively useless to another until reduced to a recognised scale. What we mean is that, if in using (let us say) ammonia for the alkaline developer, the experimentalist always use the same bottle, and really do count the drops, he will for his purpose get a near and, perhaps, a sufficiently close approach to exactitude; but let him employ a different bottle, or desire to publish, for the benefit of others, his method of producing certain results he has obtained, and he is utterly at sea unless he reduce his drops by means of a tentative experiment to an acknowledged standard. Whether it would not be infinitely better to use weaker solutions and measure them we leave our readers to decide.

The subject of the exact size of the drops formed by various liquids, under different circumstances, has always been an interesting one, and several tables are in existence showing the results of experiments in this direction by various chemists. They are as conflicting as interesting, and to read the details given by these experimentalists and the figures obtained is sufficient to cause the practice of dropping to be entirely discarded. When one experimentalist makes more than half-a-dozen trials of the simple act of dropping pure water out of a one-ounce phial, and, after counting the number needed to fill up a drachm, obtains results varying from thirty-four to sixty-five, and a mean of forty-eight, the absurdity of the system becomes evident, and it would be almost impossible to bring stronger evidence as to the inadvisability of its employment in any formula whatever.

We have made an examination of the various results tabulated by different workers, and compared it with one lately published by a French chemist, M. Boymond. If one point more than another about the tables impresses us it is the utter want of uniformity in all the results and the impossibility of correlating them. We extract a few of these to show our meaning.

A well-known work gives a table by Mr. Alsop, from which we extract the following number of drops required to fill a drachm measure:—

	Dropped from a large bottle.	Dropped from a small bottle.
Sulphuric acid, diluted	24	84
Hydrocyanic acid	35	70
Distilled water	31	54
Ammonia	40	48
Alcohol	100	130

Here the largest drop is over five times the size of the smallest; but we may observe in the case of ammonia that, whether dropped from a large or a small bottle, there was not a difference of more than twenty per cent. in the two results, while with dilute sulphuric acid the drops in one case were more than three times the size of the other.

Take Professor Proctor, an American authority, and we have—

	Dropped from a Minim Measure.	Dropped from a Pint Measure.
Nitric acid	44	62
Sulphurous acid dilute	49	54
Acetic acid	52·5	55
" " commercial	102	73
Alcohol diluted	124·5	98
Alcohol	143	118
Chloroform	276·5	180

In this table the irregularities are extreme. The largest drop is more than six times larger than the smallest, and instead of the invariable increment in size of the drops from a large over those from a small vessel, as in Mr. Alsop's table, we find no regularity at all. Thus, dilute acetic acid gives drops the same size almost whichever vessel was used, but the strong acid (not glacial) gives drops from the large vessel half as large again as those from the small; while nitric acid exactly reverses this, the smaller vessel giving the drop of increased size.

Still a third authority (American) gives:—

Hydrocyanic acid	45 drops.
Muriatic "	54 "
Nitric "	84 "
Sulphuric "	90 "
Glacial acetic "	120 "
Dilute alcohol	120 "
Strong "	138 "
Ether	150 "

The proportions here, it will be seen, bear no similarity to the foregoing, and in some instances are the very opposite. Thus, sulphuric acid drops are only half the size of those of hydrocyanic acid, but in Alsop's table they are tabulated half as large again!

We must say our own experiments tend more to the results shown by these last of Durand than those of Alsop. We will, however, not add to the confusion by placing them on record here, but will give the latest results obtained by M. Boymond, which, while they give a more scientific aspect to the question, are of no further practical help. He shows, firstly, that the size of the drop depends not upon the interior but upon the outer diameter of the tube from which they are delivered, the result being the same whether the tube be wholly or partially occupied by the liquid while dropping, the latter condition only affecting the speed. Secondly, that the nature of the liquid only—be it water, alcohol, ether, chloroform, &c.—and not the dissolved contents, whatever their proportion, influences the weight of the drops. Thirdly, to obtain drops of distilled water of a given size at a definite temperature, he gives the following data:—Temperature, 15° C.; drops, twenty to the gramme; outside diameter of the dropping tube, exactly three millimetres. Using such a dropping tube and making his observations with the utmost exactitude, he obtains the following results:—

A gramme of	distilled water is equal to	20 drops.
"	Alcohol "	61 "
"	Dilute alcohol "	52 "
"	Alcoholic tinctures with alcohol of 60° "	53 "
"	Do., of 80° "	57 "
"	Do., of 90° "	61 "
"	Fixed oils (variable) about	48 "
"	Essential oils " "	50 "
"	Aqueous solution, weak or saturated	20 "

Here we have results still more contradictory, and tending to prove that, after all, dropping under definite conditions may be exact. But, again, we cannot decide for our readers, nevertheless it is our earnest recommendation that a system of weighing and measuring should be adopted in all cases, and the mischievous practice of "dropping" entirely eschewed.

Our attention has been called to a proposed art loan exhibition to be held at Guildford, from the 26th inst. to the 3rd June. Landscape photographs, by residents of Surrey, will be amongst the exhibits admitted. Further particulars may be obtained from the Hon. Secretary, T. M. Brownrigg, Esq., Guildford.

From Chicago, U.S.A., we have received the first number of *Photography*—a fortnightly journal to be devoted to photography. It contains a variety of matter, of none the less value that much of it is extracted from English journals. We give our young American contemporary a cordial welcome.

The coloured afterglows, about which so much has been written during the past six months, are now seen more fitfully and less brilliantly, and we do not suppose it possible to take another photograph like that illustrated in *La Nature;* but there is still a continual discussion being carried on as to their cause, the eruption of Krakatoa being the most generally-accepted explanation. This volcanic eruption has been the subject of an investigation on account of the Dutch Government, and the astounding calculation is made by its agent that the ejected substances must have been at least eighteen cubic kilometres in bulk. Such an immense mass of what was mainly fine dust ejected to a great height in the atmosphere might well be conceived to be able to extend in a state of suspension over the whole face of the globe. At a meeting of the Meteorological Society an account was given of dust that fell on board a vessel a thousand miles away, which was clearly from Krakatoa.

In reference to the phosphorescent pictures, which, as alluded to by us, a correspondent of *La Nature* described a week or two ago, M. Léon Vidal writes to that journal pointing out, as we did, the futility of taking out a camera to get a fugitive luminous positive, and suggests that a negative or a transparency be used for the purpose—remembering that a negative will give a phosphorescent negative, while the latter will give a positive impression on sensitised paper. He recommends gelatine sheets instead of glass for receiving the paint, and green gelatine sheets for destroying the luminosity when required. To prevent the action of the diffused rays before the phosphorescent plate is quite in contact, a piece of black paper is to be placed over the sensitive surface while the plate is being lowered; it is then quickly withdrawn and pressure applied.

On the 28th ult. a paper was read before the Academy of Sciences, *On the Absolute Standard of Light*, by M. Violle, who, as we have before pointed out, proposed molten metal at the point of solidification as a standard of light. He now finds that platinum best fulfils the conditions required as an absolute standard, as it rests on a perfectly-defined and constant physical phenomenon, and constitutes a practical term of comparison with ordinary standards.

Singularly enough, the committee on standards held their last sitting upon the same day, and ratified M. Violle's conclusion. The resolution was that the practical unit of simple light be the quantity of light of the same kind emitted in a normal direction by a square centimetre of the surface of melted platinum at the temperature of solidification. The practical unit of white light is to be the quantity of light emitted normally from the same source. So, if a photographer wish to test his plates according to this standard, he will require an apparatus for melting platinum—a metal needing the utmost heat obtainable by any artificial means short of the electric current! We do not doubt, however, that ordinary gas burners will be made bearing, at a certain pressure, and with a certain kind of gas or a vaporised hydrocarbon, a definite proportion to this standard. Such a series of burners to burn ether or a petroleum of a definite character would be invaluable for plate-testing purposes, as with a single burner the intensity of the light can be regulated to great nicety by altering its distance from the object illuminated.

Photographers who travel in unfamiliar parts of the country find the use of an ordnance map almost a necessity. They will be interested to learn from a "blue book" recently published that the only parts remaining to be surveyed are the counties of Anglesea, Carnarvon, Dorset, Pembroke, and Radnor, and that at the present rate of progress the whole country will be surveyed by 1888, and the maps published in their entirety by 1890.

M. de Forcrand has been investigating the properties of the sodium sulphites and bisulphites, and he finds that the anhydrous bisulphite is the only one which is permanent in solution.

We learn that, so far, seven hundred tickets have already been issued to members and associates for the Montreal meeting of the British Association. Associates, it is to be understood, includes relatives of members.

MM. Parmentier and Amat have obtained crystals of hyposulphite of soda of a very unusual character. By cooling very concentrated solutions by means of a freezing mixture, in the absence of any particle of the ordinary form of crystal, they obtained crystals agreeing in constitution with the ordinary form, but melting at 32° instead of at 49°.

Hypo., it is well known, will dissolve in its own water of crystallisation, and a very pretty experiment may be thus made:—A few clean crystals—say two or three ounces—are placed in a clean flask and gently heated. After a while the whole will become fluid. If the flask, lightly covered, be allowed to cool without disturbance its contents will remain fluid at the ordinary temperature for some days. If, however, a small crystal of hypo. be dropped in, the liquid will instantly begin to crystallise, and in a short time become a solid mass, disengaging so much heat at the moment as to cause the flask to become too hot to hold with comfort.

THE LATE MR. H. BADEN PRITCHARD.

It is with more than ordinary feeling that we announce the unexpected decease of Mr. H. Baden Pritchard, for the last four years proprietor of our contemporary, the *Photographic News*. For many years previously Mr. Pritchard was well known in connection with photography, and more especially with the Parent Society, of which he was for some time Honorary Secretary, and one of the Vice-Presidents at the time of his death.

Few losses would cause a greater blank in the rolls of our art-science than will that of Baden Pritchard, and very few men leave behind them so many mourning friends in so many different circles of society. As a *littérateur*, rather than by his connection with photography, will Mr. Pritchard be better remembered by the world in general; for his energies were by no means devoted to the one subject, and his nature was to make friends in whatever circle he entered.

His death occurred on Sunday evening last, after an attack of pneumonia. The crisis was supposed to have been surmounted; but somewhat unexpectedly a change occurred, and he passed away. We reserve until next week a more extended notice of the deceased, which will be accompanied by a portrait.

The funeral took place yesterday (Thursday), at Abney Park Cemetery.

THE DEVELOPMENT OF INTERIORS.

Interiors are, as a rule, the subjects which receive the least satisfactory treatment at the hands of photographers, if I may judge from my own experience in that line, as well as from an inspection of the specimens shown at our exhibitions and in the shop windows. Yet these subjects, as a class, are the very ones which, with the expenditure of a small amount of trouble, are capable of giving the most beautiful results, whether they be selected from amongst our cathedrals, the stately halls of the nobility, or the more homely drawing-room of everyday life.

Many photographers, especially amateurs, are given to believe that interiors are difficult to photograph; and so, no doubt, they were, in a measure, before the advent of gelatine plates. Even with wet plates exposures of great length were necessary, as a rule, while the workers of dry collodion were practically out of the hunt. With gelatine plates, however, though comparatively long exposures are still necessary, or at least advisable, the difficulty of properly combining the different gradations is altogether removed; and, with careful and judicious development, it is possible to render on the same plate, with equal truth and perfection, the delicate tracery of a window outlined against the sky and the deepest shadows of the interior. There are, of course, instances which present special difficulties, as where very violent contrasts are found in close proximity. Then, again, halation has to be considered and avoided; but these cases may be met nearly invariably by a proper choice of plates combined with suitable development.

With regard to the sensitive films I for one consider that iodide of silver is a *sine quâ non* for interior work. With a plate containing a considerable proportion of iodide, and working as rapidly as the ordinary run of commercial plates, I have exposed for an hour directly in front of a window without losing a single thread of the lace curtains from halation. I need scarcely say that every precaution was also taken, by "backing" the plate, to prevent reflection from the back, the iodide serving merely to hinder halation arising chemically in the film itself.

The most common fault in photographs of interiors is excess of contrast. This lies in the very nature of the subject; for even leaving out of the question extreme cases, such as those in which a window is represented, the contrast between the well- and feebly-illuminated portions is greater than that met with out of doors. The light, in fact, coming in through one or more small openings is less diffused than it is outside, and consequently throws heavier and sharper shadows.

In the old days of collodion dry plates it was these sudden contrasts that formed the stumbling-block; for, in consequence of the disproportionate sensitiveness of the films to the differently illuminated portions of the picture, it was necessary to expose for the shadows, giving exposures that too frequently ruined the better-lighted portions of the picture, no matter how carefully the development might be effected. But the sensitive gelatine film is pre-eminently suited to the purpose of rendering these feebly-illuminated portions of the subject, and the development offers such a wide margin of treatment that the better-lighted portions may be readily held in check while the shadows are being coaxed out.

If we take an ordinary interior subject with the light principally behind or on one side of the camera and proceed to develope in the usual manner—that is to say, with the usual proportions of pyro., ammonia, and bromide employed for landscape or portrait work where the contrasts are less marked—we shall find the following results, presuming, of course, the exposure to have been sufficient. First of all the high lights make their appearance and are soon followed by the middle tones, the better-lighted portions of the subject coming up in their completeness before the shaded parts and recesses commence to show any detail. A pause now ensues, so far as the production of fresh detail is concerned, during which the image already formed goes on increasing in density. It becomes necessary to add more ammonia in order to reach the detail in the shadows; but this, while it effects the purpose thus intended, adds still further to the density of the earlier developed portions of the picture, and by the time the shadows have attained printing value the higher lights have become too dense. It is, therefore, necessary to make a compromise of some sort, sacrificing some of the perfection either of the lights or the shadows.

The result may be modified to a certain degree by developing more rapidly; that is, by using a larger proportion of ammonia to start with, or by reducing the proportion of restraining bromide. A more harmonious result is thus obtained, but it is at the expense of crispness and brilliancy. The tendency of rapid development is to produce a thin, flat image, especially in those parts which have received the greatest amount of light; and the consequence is degradation of the lights and general flatness.

If, however, we proceed nearly in a reverse direction we shall obtain an entirely different effect, and this is the mode of procedure I wish to recommend. The plan is to weaken the developer all round—that is, in all its constituents—but especially in regard to the pyro. and bromide. The result is a slower and more gradual development, and the production of an extremely thin image which is incapable of passing a certain point in density. We are thus able, by continuing the action of this weak solution, to bring out the finer details without giving undue density to the lights; in fact, we form a thin, delicate image complete in all its detail, but devoid of all density.

Up to this stage the effect of the treatment has been merely to keep back the density of the lights, without, however, destroying their power of taking on density under more vigorous treatment. Let it be observed that though I speak of the developer as a "weak solution," its weakness as a developer is confined to its inability to give density; its power of producing detail is great in consequence of the pyro. and bromide having been reduced to a greater extent than the ammonia. It is, in fact, if I may use the expression, an energetic developer restrained by simple dilution instead of bromide.

At this stage the thin image produced is capable of intensification or modification in any desired manner. The original effect of light remains nearly unchanged, and under a more robust system of treatment the high lights possess the property of acquiring density more rapidly than the less strongly impressed half-tones and shadows. All that is necessary, then, is to judge the amount of additional density required by the different portions and to convert the developer in a well-restrained, density-giving one; in other words, to add more pyro. and bromide freely, and ammonia more sparingly, until the desired effect is gained. Every portion of the already-developed image acquires greater density, but this occurs in direct proportion to the original action of light; and so any degree of contrast may be secured by suitably modifying the treatment.

With regard to the modification of the first development: this will, no doubt, vary with different descriptions of plates; but as a guide I will mention the proportions I have found to answer under my own circumstances. The plates I employ require for ordinary treatment three grains of pyro. solution, to two ounces of which I add, to commence development under *ordinary* circumstances, equivalent to one-tenth of a grain of bromide and two minims of strong ammonia. In the modified development I reduce the pyro. to one-sixth, the bromide to one-third, and the ammonia to two-thirds. Or to put it in a tabular form, I use—

Pyro.	1	grain.
Bromide	$\frac{1}{30}$	"
Ammonia	$\frac{2}{3}$	minim.
Water	2	ounces.

In addition to the greater harmony between lights and shadows produced by this treatment the effect is similar to a great increase in exposure, owing to the larger amount of detail it is possible to get out before intensification. I recommend the plan to the readers of the Journal.

H. Y. E. Cotesworth.

HE LATE DR. ANGUS SMITH AND THE ELIMINATION OF HYPOSULPHITES.

The death of Dr. Angus Smith, F.R.S., of Manchester, is announced as having taken place on Monday last, the 12th instant, at Colwyn Bay.

Dr. Smith was born near Glasgow in 1817, educated at the University of that city, and studied chemistry under Liebig at Giessen. His contributions to scientific literature were numerous and important. *Inter alia*, he was the first to recommend carbolic acid as a disinfectant. For several years he was President of the Literary and Philosophical Society of Manchester.

It was in May, 1866, that Dr. Smith communicated to the world, through the Photographic Society of Scotland, his discovery of the means by which the last trace of hyposulphite of soda could be removed from photographic prints. This he effected by the agency of peroxide of hydrogen, by which those traces of the fixing salt—which clung with such tenacity to the pores of the paper as to be got rid of only after a degree of washing to which it was not at all times possible to subject the prints—were eliminated, in the sense of being converted into another and innocuous body, namely, the sulphate.

It is scarcely necessary to observe that a particle of the hyposulphite may be so locked up in the interstices of the paper as to be beyond the reach of removal by water; but it cannot resist the application of a chemical reagent such as the peroxide of hydrogen. This body is a powerful oxidising agent, and converts many protoxides into higher oxides and several acids—the hyposulphurous, for instance—into those of a higher class. Although other substances possessing similar properties have since been discovered and made use of in this direction—hypochlorite of lime, alum, and others; yet to Dr. Angus Smith is due the credit of being the first to point out the means by which hyposulphite of soda could be deprived of its power for mishief.

It is to be regretted that the numerous engagements of this *savant* did not permit of his directing his attention to photographic chemistry to a still greater extent than proved to be the case in his busy professional life.

COLOURED AND NON-ACTINIC LIGHT.

I do not think I should have made any remarks on a matter which may, perhaps, be thought "none of my funeral," had not Mr. H. S. Starnes referred directly to some experiments, described by me, as to compounding white light out of only two colours of the spectrum. Any confusion as to the effects of successively *adding* or *subtracting* the supposed two colours in plates of glass has been sufficiently dealt with editorially, and nothing more need be said about that. But some confusion of ideas respecting the whole matter seems very general in some other points, which a few plain words may do something to clear up.

First of all, I should like urge very strongly a purely practical suggestion. It is, simply, that everyone who makes experiments or investigations in connection with this matter at all should do so with a small direct-vision spectroscope constantly at hand. Such can be obtained now for a very small sum. The cost even of one which will divide the two D (sodium) lines is not very great; and it would more than save its cost in avoiding useless experiments and in preventing mistaken notions which confuse and throw one off the track. There is the notion, for instance, that any kind of light can be "converted" into some other kind.* If it were so—if, for instance, a red glass made or converted out of white or other light any *more* red light than there was before—it is plain that the spectrum, after passing through the red glass, would show *more* red than without it. The spectroscope *shows* that no light is ever "converted" in this way—that there is not the least shade more red than before; and hence people who work with the spectrum itself as their test never fall into these mistakes. They soon learn, in a way *no* reading can teach them, that all colours, except original coloured flames, are mere residuals after more or less colour has been absorbed or otherwise *taken out*. Moreover, one glance through the prism will show instantly whether or not any given glass, or paper, or gelatine has the qualities which make it decently promising for any given purpose.

In the next place: not only is it perfectly possible to compound a white light out of green and reddish, but for all practical purposes it can be done by sending the light through coloured glasses. A room in the front basement of my house has blinds, for privacy, glazed with lozenge-squares of variously-coloured cathedral glass. There is no set pattern or order, but the various colours are fairly balanced; and there is no effect of colour thrown on the floor at all. Now, in the same way, if we have found, or can find, any sort of green glass and red glass which answer the required conditions—if we glaze one side of a lantern with alternate narrow strips of each colour, and an inch in front of this (by "in front" I mean *further away* from the light) arrange a piece of ground glass still further to cross and diffuse the coloured rays—we shall have the white light desired.

Whether it be desirable is the next question, and leads to the further question of "*non-actinic*" light. I perceive the notion is still very general that the so-called "actinism" and visible light are bound up separately, as it were, in the rays, and can be detached, so that we may have the "light" without the "actinism." This is all a mistake. Science, so far, knows nothing but certain *periods of vibration* in the ether. Some of these come within visual limit and some not. Some which are too slow for vision are adapted to set swinging the heavier atoms of gross matter, and so produce heat. Some which are too swift for vision set up other motions, which produce energetic chemical effects. Thus it happens that yellow light produces very little effect of a chemical (photographic) kind upon the salts of silver which were employed in early photography, and so it used to be said they were chemically "inactive." But these very rays are among the *most* active in producing vegetable changes, which are also chemical effects; and thus every rate of motion has its own special aptitudes.† And there is *no* "non-actinic" light whatever, as Captain Abney has shown already.

* In fluorescence, where invisible or infra-violet rays are made to yield visible rays, there may be thought to be an exception; but there is no direct "conversion" even there. Vibrations which are too short and quick to be seen set up vibrations in the atoms of the fluorescent substance, and these originate *new* vibrations which are within the limits of vision.

† A familiar illustration may make this a little more clear. We may drop a hammer, with a nearly flat face and weighing four pounds, from a height of three inches upon a planed iron surface; the latter will not be appreciably dented. We can calculate, from the weight, height, and velocity at impact the exact momentum of the blow, and we may adjust the blow of a small hammer weighing a-quarter of an ounce so as to give precisely the same momentum; but in this case a very conspicuous dent will be made in the iron. The same mechanical energy applied in rather different form is adapted to produce very different effects.

The nearest to it would be this, which will show us the next essential in systematic experiment:—Suppose we have a bromide plate prepared in any given manner, and we throw upon it a spectrum from (say) the oxyhydrogen flame: the solar spectrum is unsuitable, because its dark absorption lines would lead to error; we must have a *continuous* spectrum. Giving a fair exposure and developing, suppose we find in some part of the spectrum a band which is *absolutely unacted upon:* in that case, could we find a coloured light whose visual spectrum answered to that band *and no other* we should have what we wanted. But even then it would only be for that particular formula, and the least variation in the condition of the plate used would do away with the absence of chemical action.

It is doubtful whether any band of absolute no-action could be found with sensitive plates and good exposure; and, did the problem practically lie in finding such a colour, it would be insoluble. Fortunately it does not. There is a wide difference in the *amount* of chemical action, so that with *short* exposures *nearly* inoperative bands can be found in the spectrum. And, secondly: it appears well-established that some *small* amount of exposure in preparation is actually essential to sensitiveness itself, though too much spoils it and causes fog. These two facts make the problem practicable, and define and simplify it. We cannot possibly find "non-actinic" light; we may find that which combines with most visual power and least visual injury the amount of chemical action which is desirable, and no more. Obviously we must find this most quickly and most certainly (1) by finding the *least* actinic bands in the actual spectrum on the actual plates to be used; and (2) by finding, with the prism, coloured glasses or other media which correspond with these bands. Any other method is a kind of "hit or miss" that is sometimes necessary, but which, when better methods are accessible, is like groping in the dark.

Tracing the matter thus, general experience is that red light beyond a certain wave-length is the least actinic over a wide range of bromide plates. But, in spite of individual opinions, the general demand for some other colour, Mr. Ackland's experience as an oculist, and a variety of other evidence, go to show that the colour is often painful and generally injurious. And now the practical problem is of this sort: by adding green of certain wave-length to it, as suggested by Mr. Starnes, and which is perfectly practicable in the way above suggested, we can produce white light which will *not* be painful or injurious, and gives far more visual power to average eyes. But the green to be added is, undoubtedly, considerably *more* actinic than the red. The main question, therefore, is simply whether the increased visual power from the added colour will allow of the *total light being so far reduced* as to leave the action on the plate within the allowable limits. If it do the photographic object is secured; and, while the eyes of the operator may not possibly have actually *more* light to work by, they will, at least, have it in a better shape and free from the irritation of the colour. The same applies to a yellow light procured by various expedients,* or to any other.

Such is really the essence of the whole question. "Non-actinic" light will never be found; the limits of *permissible* actinism for any given plates may be found. That is a research with the purpose of finding quantitative conditions in two directions. But the research ought, I think, to be carried on systematically, by the methods indicated, if the best results are to be reached with the smallest expenditure in material, time, and trouble. LEWIS WRIGHT.

ASTRONOMICAL PHOTOGRAPHY IN FRANCE.

OUR contemporary, *La Nature*, had a week ago some interesting remarks upon astronomy and photography, and accompanied them by an engraving from one of the negatives obtained by the French expedition to observe the solar eclipse last year. "The applications of photography to scientific research," it says, "multiply daily, but the results that it has obtained, astronomically considered, are especially remarkable, and the study of the sun, moon, eclipses, and even the stars have of late years received most valuable aid from it." The great advantage of photography, as M. Faze says, is to banish the observer and to replace his eye and his brains by a sensitive plate which receives and fixes the phenomenon without any need for his lying in wait for it, gazing at it with painful assiduity; and it further entirely protects it from those errors inseparable from rapid observations.

* I think sodium light would be worth experiment; and I may remark here that, as ordinarily produced, it is by no means *pure* yellow, which may injure results. There is considerable blue light in either a spirit or Bunsen flame; and this must be stopped before the performance of the yellow can fairly be judged of.

Describing the mode of taking this photograph, *La Nature* quotes M. Janssen as follows:—"Two large apparata carrying eight cameras were prepared for the purpose of studying the question of intra-Mercurial planets and of the form and extent of the corona. As to stars and planets of the circumsolar region, these photographs will require close examination; but with regard to the corona it may already be stated that the focal power of the objectives employed (eight inches and six inches), and the length of the exposure, enable us to say that the corona has a much greater extent than an optical examination would show with either the naked eye or a lens. Several of our large photographs of the sun are very sharp. They show important details of structure which will require discussing. The form of the corona was unchanged during the whole of the totality."

The photograph, which has also been reproduced in the *Annuaire du Bureau des Longitudes* for 1884, has been neither retouched nor enlarged. It was taken with an eight-inch objective of 1·20 m. focus, exposed during the whole of the totality (about five minutes), and, as our contemporary justly states, gives promise of a great future for astronomical photography.

THE LANTERN.

WITH the long days and light evenings the season for lantern work may fairly be said to have closed, and the present is, perhaps, an opportune time for making a few suggestions on the treatment of lanterns and apparatus. I have seen really first-class and expensive instruments, after being a short time in use, in such a condition that should only be possible supposing they had been employed for several years. The reason is (to sum it up briefly) "insufficient care." One would naturally think that we should not require to be told that it is necessary to look after that which has cost us a considerable amount to obtain; but, from practical experience in the matter, I can assure the readers of the Journal that such is the case, and trust they will accept the following hints with the assurance that they are given in the best spirit and in the hope that they may prove advantageous.

All brass-work should be carefully wiped *directly after use*, so as to remove finger-marks; for these marks—especially when made by warm hands—soon eat into and stain the brass, and in the case of sliding tubes prevent their working properly. In oil lanterns the lamps should be taken out of the lanterns and carefully drained of oil, and any spilt oil wiped up with tow or flannel.

Lime light lanterns should have the jets taken out, the lime-holders brushed, and all steel parts wiped with a slightly-greased rag or flannel. The trays should be freed from lime dust, and the body of the lantern dusted out, so that all crevices may be cleared. The dissolvers and all stopcocks should be taken out (one at a time, so as not to get interchanged) and wiped with a greasy rag. Benzoline is a capital cleanser and also lubricant for parts much corroded. The tin-work should be rubbed over with a piece of cotton wool having a little sweet oil on it, and the wood-work can be preserved and revived by being gently rubbed with a tuft of cotton wool inside a soft rag, damped with a mixture of equal parts of linseed oil and vinegar and half quantity of methylated spirits.

The lenses should be wiped with a soft and clean chamois leather and then gently warmed and wiped again. After this they should either be wrapped in a soft leather or done up in tissue-paper first, and then in brown paper; or a wad of tissue-paper should be placed before and behind the lenses in their mount. If the polished parts of brass-work are very much marked, then a little rotten-stone and oil should be put on some cloth and the part polished by rubbing in *the same direction as when made*, which will easily be discerned when looking at it. All telescopic tubes should be polished *length-wise*, and care must be taken to remove the flanges and so get a good movement up and down. All remaining grease, &c., should be taken off from tubes and edges, so that the brass-work is left dry and clean. Lacquered work should only be wiped.

Some finger-marks that resist a dry leather will come off with a damp one; but in no case must much force or friction be employed, as the lacquering will not stand it, and relacquering is somewhat expensive. In some instances a rag very slightly oiled will sometimes clean lacquered work nicely; but all must be finally gone over with a clean, soft rag or leather.

Before placing the instrument away for a long period, see that all parts are thoroughly clean, as explained, and find a *dry* store-room in which to place the apparatus. If any doubt be felt about the only available space, then dry the box and apparatus thoroughly, and paste strips of brown paper round the doors, over keyholes,

&c. Unless sure of the room being kept at a temperature of 40° or more, then the india-rubber tubing should be taken off before placing away, and kept in a drawer that is warm, coiled round in a circle, so as not to get set in bends.

Neither in storing or travelling should any hard substance be placed loose in the box, as the wood-work and brass mounts soon get damaged, and it is very easy to wrap up any extra piece of apparatus in baize, cloth, linen, or even soft paper to prevent harm. Gas bags should be well rolled out and warmed; then folded in their entire breadth into (say) three parts, and carefully wrapped in brown paper and stowed away on the top of or inside a warm and dry cupboard. All retorts, purifiers, &c., should be well cleaned and thoroughly dried.

In no case should the leather used for the lenses be employed for any other purpose, and it ought to be always shaken before use, so as to remove loose dust. The lenses should also have any loose dust blown off before wiping. The lanterns would not get injured nearly as much as they often are if care were taken to turn on the hydrogen only a little at a time, and mixed with it, *by degrees*, the oxygen.

G. R. BAKER.

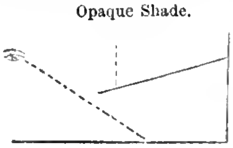
THE "HAPPY MEDIUM;" OR, DARK-ROOM ILLUMINATION.

IN THREE CHAPTERS.—CHAPTER III.

NOT only have we a choice of colour to suit our individual taste—not only can we choose between a transparent and a translucent medium—not only have we at command sunlight and artificial light, but we have the choice of ways by which our light can be made to reach our plate and our eyes. This opens another most interesting subject. It is perfectly certain that light reflected on to a sensitive plate is safer than the same light shining directly upon the plate, while a light may very easily shine directly upon a plate or be reflected on to it without our eye being within the influence of the light at all beyond the time when the light is purposely reflected into our eye—beyond the time, in short, when we are looking at the plate. This arrangement exists in more than one studio and amateur's laboratory with which I am acquainted.

I attempt to give a drawing of what I saw in one place in Edinburgh, and even my poor sketch explains itself. Here the light does not directly strike the eyes at all, and the plate can be most carefully examined without any strain or glare affecting the eye.

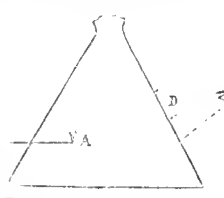
Opaque Shade.



Light

Plate.

In another arrangement the light is cast straight down upon the plate from the translucent bottom of a triangular lantern, of which I show a section. A is the source of light; a gas jet, B C, a translucent bottom; D a glass window, shuttable at pleasure, through which the plate can be examined by transmitted light when required—the plate being developed below B C, and the eye being opposite the opaque side of the lantern, but able to see the plate below if the lantern be swung at a proper height. The latter I saw in the hands of Mr. Wardale, an ingenious Edinburgh amateur. For comfort and safety to the eye both of these arrangements serve admirably, and the plates under development can be examined even more satisfactorily than with the glare of the coloured light shining into the eye. In fact, I mean to adopt both the methods in my own dark room, and I can give them no higher testimonial.



If in spite of all ordinary precautions anyone finds pain or mischief to arise from sudden emergence from the dark room into brilliant light, I would further suggest a practice recommended by some writer whose name I forget, namely, to have in a convenient spot near the dark-room door a pair of blue or natural tint "goggles." A few moments' wear of these on first encountering the bright white light would remedy to a great extent the evil that might arise to weak eyes.

All that I have yet written on this subject appears disconnected and rambling, and I only regret that my conclusion will still leave the question an open one. But if the question is by its nature an open one, so it ought to remain; and I think that within certain limits the matter should be settled by every man according to his own taste and manner of working. For my own part I require to examine the plate very carefully during the earlier and latest stages of development—during the period when the image first comes up—in order to determine what steps I shall have to take later, and, when development is almost complete, in order to be prepared to stop the process at the proper moment.

I have, therefore, determined how much red light I can use for a certain time transmitted by a certain medium without danger to my plate. Of that quality of light I use the utmost safe quantity in ordinary circumstances, shading my plate entirely from light when I am not examining it. When a more protracted development and more careful, frequent, and prolonged examination is required, I simply add to my ruby glass a yellow one. If I liked the yellow-green light I should act precisely in a similar manner. In a strong light, or during a protracted examination of the plate, I should add to my yellow window a layer of medium over and above what I found requisite under average circumstances.

I intended to finish these remarks at this stage, but I have just seen two articles in the Journal of to-day's issue (25th April). I came upon Mr. Starnes's remarks first, and I was as much "flabbergasted" as puzzled until I reached the editorial postscript to the chapter. Mr. W. H. Harrison's remarks, however, are more or less *ben trovati*; though some seem to "go without saying," some to be doubtful, and some totally contrary to my theories on light matters. Mr. Harrison "comes in like a lion" with (A) "Daylight should never be used," &c. His chief reason is that it is "enormously rich in actinic rays," &c. Illumination and actinism are more or less inseparable, and I find daylight not perceptibly richer in actinic force, *in proportion to illuminating power*, than artificial light, so I simply use less daylight than I should candle light. For my own part I always use daylight, though I have many kinds of dark-room lamps. When I have great numbers of negatives to develope I rise with the sun, but never develope by the gas. The same remarks may apply to his B, and even to C. If a translucent screen be used more light is required; but I am willing to admit that to some persons a diffused light is more pleasant.

As to Mr. Harrison's proposition D I speak with some diffidence, for I have not worked it out. His theory appears to be that light thrown on a plate at an angle of (say) 50° tends to fog it. But, as Mr. Harrison says, light cast at an angle of (say) 40° is reflected into space from the surface of the developing solution. Well, is that not simply light lost, so far as seeing the plate is concerned? If not, I have misunderstood Mr. Harrison. I agree with Mr. Harrison so far that the lantern should be large enough to illuminate the entire room; but, as I said before, I recommend that the eyes should be shaded from anything like direct light proceeding from the radiant. Even with translucent filtering media the diffusion is not perfect. F seems to me partly a truism and partly incomplete. I could suggest a safer than his "safest," by substituting for his "a yard" my own "a mile." If he mean that, when using a light not altogether to be trusted in ordinary cases, it is advisable not to approach too close to the light until it is necessary to do so, then I am entirely with him.

Mr. Harrison, under G, says no two coloured screens of the same material should be used in the window of one lantern. In detail he says this proposition "needs no defence." He partly saves himself by the words "by its colour." But the bare proposition G needs more defence than is likely to be forthcoming. Does Mr. Harrison mean to say that a glass flashed with ruby on both sides is no better than a glass singly flashed? If he do mean that I must refer him to the editorial remarks on part of Mr. Starnes's paper. Or does Mr. Harrison insist that a single screen of a certain colour must of necessity filter out the whole of any particular class of rays? If Mr. Harrison filter a solution once, does he never by any chance repeat the operation with a second filter? or does he never use a double filter paper for the first operation? That a double thickness of any material stops a certain amount of light no one will deny, but that a double filter of rays or anything else can do no more than a single one is a statement that will require very able defence indeed.

Mr. Harrison's concluding proposition is worthy of respect on account of its boldness—how much further I do not take upon me to say. Even Mr. Debenham—the champion of green light in combination with yellow—has not, so far as I know, made a statement so sweeping in its application or so emphatic in its phraseology as Mr. Harrison's H. Mr. Debenham has, no doubt, his reasons for recommending his shades of green; but Mr. Harrison says the blue rays of light must be "sharply" cut off for developing purposes. Has Mr. Harrison really found a green that, either alone or in combination with any pale yellow material, will cut off "sharply" or otherwise all the blue rays? If my two spectroscopes are to be trusted, I have not yet discovered any such combination, and many have been my examinations of various substances brought before me in these columns and by private individuals. As an argument against red or yellow rays Mr. Harrison adduces two statements of his own, of which one is—that if fields and forests were all of these hot colours we should all soon be blinded. I take it that our eyes are subjected constantly to much greater heat than is produced by colour, and yet I for one claim to have pretty fair eyesight. But I have no mind to take up further space, and I shall conclude by stating as succinctly as possible my ideas on the subject we have on hand. I have commented on Mr. Harrison's paper partly because it is a strong and able defence of its writer's principles, and partly because it happened to come before me as I was writing on the subject. All I wish to do is to protest against any rules being laid down by one person for another on matters which, in my opinion, depend on taste.

The media most in vogue at present are ruby glass with or without yellow, and with or without diffusion, combinations of green and yellow, and the greenish-yellow of canary medium. To these I may and papers of various orange colours, oiled and plain. Let the photographer take the one of these that he likes best, try his most sensitive plates under the most crucial tests likely to be required, use the most light he can with safety, pay his money, and—"take his choice!"

ANDREW PRINGLE.

PHOTOGRAPHERS AND SITTERS.

[A communication to the Edinburgh Photographic Society.]

PHOTOGRAPHY being a comparatively recent art, the photographer—perhaps much oftener than in other professions—is still found to be a man who did not begin his business life in acquiring a rudimentary knowledge of it in youth. In a large number of instances he will be found to have come from some other field of industry, and no doubt this will always more or less hold. So far as I have observed, no particular trade or profession has more largely than another been relinquished for the camera; but it has attracted all sorts of votaries, varying much in their capabilities. But time goes on, and, while much remains the same, we find in the ordinary course of things new conditions arise.

Rapid changes in our art soon make the past grow old. The collodion age, with its capricious baths and laborious manipulations, has practically passed away, so that the present generation only know part of the troubles and difficulties of earlier workers. Many of us know nothing of them, and the rising generation will read of them as ancient history, while doleful tales could be told of these old troubles; but I forbear, except to make one reference. One of our most eminent members, whose experience goes back to daguerrotype times, related to me the other evening how he had once been driven to the verge of distraction through a mysterious spotting of his plates a few hours after they were taken. He was harassed for days and nights to find the cause, till at last, about two o'clock one morning, his sleepless mind hit upon a probable explanation. He immediately left his restless bed, went straight to the studio, and found he was right. It was a very simple matter, and so do all our old vexations seem when they are past; but we may never cry too loudly, for we are seldom very far out of the wood. In proof of this I may just mention that, at our last meeting, a member who makes capital gelatine emulsion was describing how he had come to grief with something like pinholes in his plates, and was quite baffled to discover the cause. So it goes round. Old faults are overcome, while with the advance of processes new troubles arise and task our patience and carefulness. Perhaps it is better that this should be; but I need not moralise upon the uses of adversity, as photographers have some acquaintance with them.

I have just used the designation "artist" without staying to inquire concerning its suitability, and I think you must all be quite satisfied that more than enough has been written and spoken upon the question whether it be proper or not to apply it to the photographer. The seductiveness of the word to many, doubtless, lies in its desirable associations.

In the atmosphere of the Edinburgh Photographic Society—which I suppose is the largest in the world—we occupy a pretty favourable position from which to form a general idea of the class of men composing our order, both professional and amateur; and, visited as we are from many quarters by gentlemen of distinguished position in the art, I think a favourable impression must prevail as to the fraternal interest commonly manifested in what relates to the objects for which we seek association.

In reference to the subjects upon whom we operate (for the somewhat anatomical term "operator" is in familiar use amongst us) many have been the published hints and suggestions offered to gentlemen in our profession as to how best to treat their sitters artistically—not customers, mark you; that would not be a proper term, for photographers have no customers. We all know that certain words are appropriate, or the reverse, as the subject varies to which they are applied. It is not for a moment permissible to think of Sir Frederick Leighton speaking of his sitters as his customers. That style of speech belongs to other, though not less worthy, folks, such as cotton kings and merchant princes—in common, however, with sweeps, costermongers, and an infinite number of other legitimate callings which the law of usage has embraced in the matter. But the photographer—very high on the one hand and very humble on the other—for some occult reason, probably the same that rules the Royal Academy, has never come under this latter rule—never to my knowledge. He was a very timid man at first, I believe, and did not for some time speak of his studio; but the idea rapidly grew upon him, for his is an eminently progressive mind, and so from modestly speaking of his *skylight*—for which see his ancient advertisements—he now alludes without any hesitation, as he is properly entitled to do, both to his studio and his *sitters*, sitters and portraiture being associated as indissolubly as doctors and patients. Another word is indeed sometimes used when we are taking very fine "shop"—I refer to *clientèle;* but its use, though perfectly legitimate, is still select, and perhaps exclusively employed in our literature as yet.

However, be they called "sitters," or by any other term, a good deal has been written as to the most artistic manner of treating them with a view to the production of pleasing and successful portraits. Many very good and useful things have been said, and much that is of no practical use to anybody. But, while thankful for a good hint, of course every man has an individuality of his own, and in his own house will more or less make that felt, managing his own affairs in his own way. It is one of the charms of life that we are not all of one uniform pattern. A compelled dead level in human works and ways would be uninteresting and depressing. It is well that a man's work should bear his own stamp—that being as excellent as possible.

It is the case, generally speaking, that a person who steps into a studio for the purpose of having a portrait taken does so in what may be called a "smiling frame of mind." The idea is commonly looked upon more or less as a sort of joke, or at least something that is alluded to with a smile, and as if the proposal needed just the faintest approach to an apology. Whenever this is observed—and it will be often—it should be accepted as the keynote to what intercourse may follow. Other sitters come in serious moods. Partings and unhappy events bring business as well as joyful occasions. Death itself at times demands our services, and thus we do not always work under the most favourable or cheerful circumstances.

If, as Pope says, "the proper study of mankind is man," perhaps in this matter of portrait-taking we, who are engaged in it, see as considerable a share of the human nature about us as most people who serve the great British public; and while comparing one class with another, and noting differences in the manifestation either of weakness or of general social culture, we find there is a wonderful family likeness running through it all, and to the thoughtful man it is most instructive. Some studios, of course, invite, in the very nature of things, certain classes. In some the comparatively poor man is never seen, and in others, again, the aristocrat is a *rara avis*, or unknown. The experience of these two extremes in many respects are very different, and both present advantages or difficulties of treatment peculiar to themselves. The better classes, without question, are, for example, more refined in feature, and, of course, much better dressed. The sanctity of the æsthetic hangs about them all, all of which are distinctly great advantages and aids towards successful portraiture. The educated face in any class has generally an indication or suggestion of something superior behind it. Low caste or very unintelligent features do not attract the interest of any one, save it may be as a study of physiognomy. But there is another and very valuable aid afforded by the better class of sitters: they more easily assume a graceful or picturesque pose. The habits of good society powerfully lend themselves to this, and there is less failure through awkwardness in disposing of the hands than in the commoner classes of society. Any one who has had a little experience in the profession will readily appreciate these things as matters of fact.

Apart from the question whether a portrait has pleased the sitter or not—for that is a matter distinct by itself—picturesqueness, elegance, and attractiveness are all often secured in a portrait without any but the minimum expenditure of skill and tact on the part of the artist when the subject is a favourable one. Perhaps the professionals into whose hands this superior grade of subject usually falls may not be quite willing to admit much on this score which would at first sight seem to lessen their artistic capabilities, but there is no necessary connection. Subjects vary immensely in the facilities they afford for good composition, and so on; and I believe it will be agreed that it actually demands from everyone more tact and knowledge of effect to make a passable picture of a commonplace subject than of one of a higher type. That, I think, ought to be obvious at a glance. I do not now, of course, refer in any degree to *genre* pictures, where, in the very excess of the homely, rags and dirt even may be made to look delightful; just as (to take an illustration from a different kind of subject) a picture of a cottage (say) taken when it was built may be extremely commonplace, but when it has been vacated by its last tenant, and the hand of nature, with its inimitable touch, has pulled its walls awry, dilapidated its roof, and generally tinted it over with its own glorious colours, then it has become, as by a witching process, a thing of beauty. A beggar could not sleep in it, yet might its art presentment adorn a palace.

Perhaps I may be permitted to touch briefly on a few of the characteristics and odd points occasionally met with in sitters in our everyday practice. Popular ideas about portraiture, as about many other things, are often erroneous. Among these I would mention, for example, the notion commonly entertained that the photographer will do all that is required himself. "He knows best," and so he does doubtless; but Giles and his sweetheart go into the studio as nearly as possible in the character of lay figures. They have an honest resolve to be docile in order to get a good likeness, but wanting in intelligent conception how to assist to this end. This sitter is probably more frequently found in the shape of the country cousin than the town one, but they come from all quarters. When the lay-figure sitter is taken to be posed his distressing condition is most vexatious and trying, and it taxes the artist, who had better smile and bear it, to get him by any kind of artful byplay to feel at his ease and to relax the rigidity of his muscles; but no one unacquainted with the actual fact in extreme cases could fairly credit how difficult is the task. The sitter is gently inclined a little to this side or to that, and he mechanically obeys with all the elegance of a leaning chimney-pot. But there is one grand feature about this man: he never asks for credit—unlike my Lord

Heavymasher, who may give a world of trouble, and to whom the idea of cash payment is "bad form."

When a portrait is criticised and condemned, the difficulty of the subject is seldom considered. It is the operator who is blamed; and that he is often enough at fault I suppose none of us will deny, but in many instances he may do his best and fall short of all he could wish. It is not sufficiently understood by many that whatever peculiarity of expression is worn during the sitting that must be reproduced in the photograph, such as tight-set lips or elevated eyebrows. Nor, again, is the effect of certain little covert movements, sometimes indulged in, correctly reckoned upon. Miss Jones, for instance, stands pleasantly as placed, and all seems finally arranged for the moment of removing the cap, when she executes a little manœuvre on her own account by shifting a hand or rearranging something that has not been to her mind exactly, which may turn out all right, but is quite as likely to be all wrong. In this same connection sitters will occasionally allow themselves to be posed with the head-rest; but having a dislike to its use, from the impression that it makes them look "stiff," they quietly remove their heads from it at the moment of exposure, and by so doing generally expose their having done so.

Ladies very generally miscalculate the effect of *primming* the mouth. That feature is one over which, after a comparatively early age, they manifest a great solicitude, and it is precisely on account of this anxiety where the danger arises of a slight distortion. I need scarcely remark that it almost invariably takes the form of contraction. I make these remarks out of a deep respect for them, and a desire to see them fairly represented. But the weakness is not exclusively confined to one sex, for I have seen fellows with moustaches do it. How sitters can ever forget, or not imagine, that, in the strain after an effect, the strain itself will be visible in the portrait is difficult to account for; but it is as common as portrait taking.

Another great blunder made is to suppose that the more unconcerned and indifferent one looks the better it will be. Under this impression we all get visitors who want to be taken with their legs and arms sprawled over the place, or they dump themselves down in a heap before the camera in defiance of every grace or form of gesture that has been known to man.

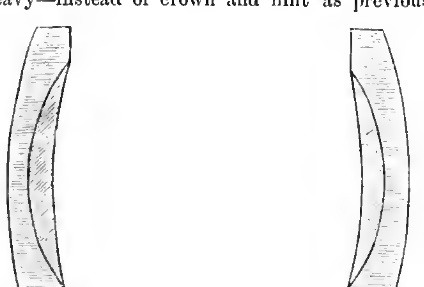
Again: we have a visitor who had once been young, and it may be blooming, who, after looking at various styles of work, will, in conclusion, point to some pretty girl's portrait, and, apparently oblivious of any difference in the original, gives us a commission to "take me just like that." How is it possible in these circumstances to explain the impossible, even in the most gingerly-chosen terms? It is better to do your best and leave the rest to fate, which is often very kind.

What I have said has had reference to studio work. There are other phases equally fruitful of remark, and I might have gone on to draw thus upon photographic memories and experiences; but enough, I think, has been said to make good the title of my remarks this evening. I have recapitulated a few of our difficulties and business characteristics, and the purpose they may serve may be regarded as merely relieving our severer studies and technical discussions. I apprehend that in our meetings the lighter as well as the more weighty matters of the law legitimately find a place, with the double object in view, understood if not expressed, that our friendship socially, as well as our advancement photographically, might be fostered and increased.

G. G. Mitchell.

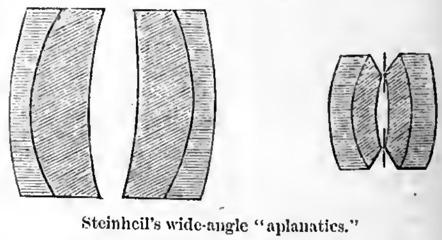
ON LENSES.*

A new departure was made by Steinheil in January, 1867, when he introduced the lens which he called "aplanatic." I think it only just to express my belief that photographic history will accord a place to the genius displayed in the various introductions of Steinheil only second to that of Petzval. The peculiarity of this lens consisted in the glass of which it was composed being of two kinds of flint—light and heavy—instead of crown and flint as previously. By this



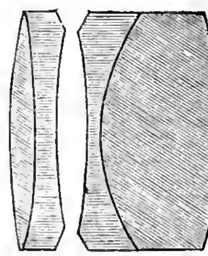
Steinheil's "Aplanatic" Lens, rapid form

means it was possible to so far reduce the spherical aberration that a much larger aperture could be employed than with any previous cemented photographic combination. This lens, with a power of light unequalled in any previous combination, except, of course, the portrait lens, had its field considerably flattened, and embraced a rather wide angle. The instrument is symmetrical—that is, the back and front are alike. The lens has had the sincerest flattery bestowed upon it in the manner in which it has been imitated by all the leading photographic opticians Differences of workmanship, of course, influence the results produced by different makers, but it is very doubtful whether any improvement has arisen from any little variations from the original calculations that may have been adopted by any particular manufacturer. The landscape and wide-angle aplanatics by the same optician have met with similar flattering treatment by other makers, though not, perhaps, to so great an extent.



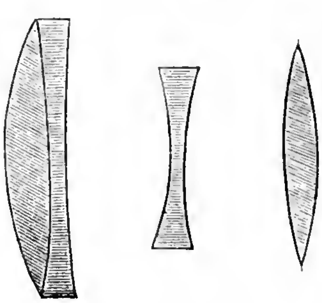
Steinheil's wide-angle "aplanatics."

We now come to another lens of Steinheil's which is as yet scarcely known in this country. It is, or, rather, they are—for there are two distinct varieties—called the "antiplanatic." One of them, called the "group antiplanatic," consists of two cemented combinations set so closely together as only just to allow of the insertion of the diaphragm. The front lens is of shorter focus than that of the whole combination. The back lens, when looked through diagonally, diminishes very powerfully and lengthens out the side pencils of light proportionally. By this means the field is much flattened, and the spherical aberration is so far remedied that it has an angular aperture giving a rapidity about equal to what would be No. 2½ on the universal system—less than half that of an ordinary rapid portrait lens. No doubt it will work better with rather a smaller opening, but for large portraits it is seldom, if ever, desirable to use a stop giving more rapidity than No. 3; and with our modern rapid plates smaller stops than this are generally employed. For ordinary portrait use it seems to me to be a very suitable instrument. However, I should judge that it is rather a difficult and expensive instrument to construct; but, unless other makers are deterred by these considerations, I should by no means be surprised to find it largely adopted as a model.



Steinheil's "group antiplanatic."

The so-called "portrait antiplanatic" has the back elements separated like that of Petzval; but, like the group antiplanatic and the orthoscopic, the back as a whole is negative. Astigmation has been wonderfully got rid of; but there is an amount of curvature of field which renders it unfit for working upon a large field, for which, however, it is not intended.



Steinheil's "portrait antiplanatic."

Lenses there are—and very good ones, too, some of them—bearing other names than those I have mentioned, and some photographer may think that I have omitted speaking of his pet instrument. If he will carefull examine that instrument, however, it is probable that he will find it included in one of the typs described. Where the difference is not marked, and the particulr details of construction have not been published, it could not be expected that they should be here specified.

Having now gone through these types, the question arises—"Whe is the best lens to use for any particular purpose?" To say that for rapid portrait work the Petzval form still holds its own, and that for lndscape—when rapidity is not required—the old single view lens is ard to beat, seems to suggest that no improvement has taken place within the last forty years. It is, however, in lenses for other purposesthat improvements have taken place. If it be desired to obtain the most perfect delineation of any particular subject, including nea and distant objects, irrespective of size of picture, that will be best secured by a lens of short focus. If it be desired to cover a ertain-sized plate, and there be a latitude in the amount of subjectto be included, or in the distance from which it may be photogrphed, choose a lens of long focus. This is particularly the case with nstantaneous views, where a small stop cannot be employed, and fr these reasons:—The field of a lens such as must be used is always urved. Now, the longer the focus the larger is the curve, and a lin of any given length—the side of the plate—will lie nearer to theircumference of a large circle than of a small one. The views of achts in

* Concluded from page 297

full sail now shown were taken with a Steinheil aplanatic of about seventeen inches focus. The length of the plate is about one-half that of the focus.

For portraiture, for the same reasons, flatness of the curve of definition, less departure from the focal plane, and the use of as long a focus lens as will take the subject of the required size, will conduce to the general sharpness of the result. An occasional objection to the use of a long-focus lens for portraiture is that in certain weather, especially in towns, the fog or illuminated smoky atmosphere between the lens and the sitter, destroys the brightness of the image, and the nearer the subject can be approached, the less this is felt.

For copying flat surfaces, to avoid the curved field the longer the focus the better, and I think that for this purpose a lens might be introduced having its normal field—that for parallel rays—convex. Astigmation and spherical aberration might abound, but stopping down would do a great deal to get rid of these evils, and for even delineation all over the picture, it is better to be *in* a rather bad focus than to be a long way *out* from a very good one. For architecural subjects there are to choose from, the flatter curves of the modern lenses made upon the symmetrical aplanatic plan, and the rounder curves of the earlier lenses that have been described. For very wide angles the rounder curves have an advantage in transmitting more light towards the edges of the field, as it strikes the lens nearly at right angles, and so less is lost by reflection. The flatter lenses, however, have less spherical aberration, and thus permit of a larger diaphragm being used; but when a very wide angle is desired—unless in the case of an interior, or with the sides of the subject advancing considerably—a small stop is absolutely necessary for good definition.

In addition to the panel portraits taken with the single Grubb lens, I have here some of the same size taken with the Steinheil aplanatic, and some promenades with a very similar instrument—the euryscope of Voigtländer. Here are also photographs of a sitter with accessories and scenic background, taken with eight different lenses without altering the position of the camera. These were all worked with apertures No. 3 on the universal system, and it will be seen that there is little difference in the results when thus brought to the same level. The lenses are portrait lenses by two good makers—a euryscope, a French lens on the Steinheil aplanatic pattern, an antiplanatic portrait, and an antiplanatic group, both, of course, by Steinheil. Here are also some scenes taken by Mr. Haddon with a euryscope of eight inches focus. Although the plates are nearly of the same length as the focus of the lens the definition is remarkably good. Of course, when this angle is included a small stop is used. W. E. Debenham.

Addendum.—I have been requested by a member to state how to calculate the focus of two lenses when combined in a doublet. Make the focal length of each lens the denominator of a fraction whose numerator is unity, and add. To those unaccustomed to arithmetical calculations an example may make it clear. Say that two lenses—one of twelve-inch and the other of ten-inch focus—are to be combined. Add $\frac{1}{12}$ to $\frac{1}{10}$ by bringing them to a common denominator; that is, $\frac{5}{60} + \frac{6}{60} = \frac{11}{60}$. Now reverse the fraction—$\frac{60}{11} = 5\frac{5}{11}$—and the lens is found to have a focus of $5\frac{5}{11}$, or just under five and a-half inches. If one of the lenses be a concave the operation is similar. Let the convex lens be of five inches focus and the concave one six inches negative. Then $\frac{1}{5} - \frac{1}{6} = \frac{6}{30} - \frac{5}{30} = \frac{1}{30}$. The compound has a focus of thirty inches. Separating the lenses will make a difference in the result, but not to an extent likely to mislead the photographer who wishes to provide himself with a set of lenses of different length of focus.—W. E. D.

RECENT PATENTS.

PATENT APPLIED FOR.

No. 7,365.—"Improvements in Photographic Shutters or Caps." William Henry Marshall, watchmaker and optician, Scarborough, Yorks.—*Dated May* 7, 1884.

Apparatus for Touching Up Photographic Pictures, &c.

The following is the provisional specification communicated by J. Geesbergen and La Societe Geruzet Freres, of Brussels, Belgium:—

The after touch on photographic pictures consists in the attenuation of the rugosity of the skin produced by transparencies on the negative, as well as unpleasant prominences on the face.

A skilful toucher up will then join in the just appreciation of the relative value of the lights and shades a great delicacy of the hand in order not to exceed the object.

According to this invention an electro toucher up is produced which mechanically produces a fine dotting by the vibration of the armature of an electro magnet carried on a pencil. All that is necessary is to place lightly this latter, on the part of the proof the opacity of which is to be increased to obtain a good result, without fearing, what often happens, a too-prominent or pronounced touching, thereby destroying the anatomy of the face.

It will be easily understood from what has been said that the electric vibrations are regular. The work will be thus divested from the nervous influence of the person doing it. It will be much more correct and more regular, besides the rapidity of execution will be increased to a very great degree.

The apparatus is composed of a bed consisting of a cupboard or case for containing the electric piles. On the top of this bed a support is provided carrying a balanced rod having counterweight and regulating screw; at the other end of this balance is suspended, by means of a string, an electro retoucher. This latter receives the electric current by means of a flexible connection having two conductors coming from an aperture formed in the top of the bed; on this same bed is placed a commutator to distribute more or less of the power desired to be given to the electric current.

It will be understood that when an electric current is brought into the electro magnet its armature will oscillate and will cause a block or stock to vibrate in a corresponding direction to which the pencil carrier is fitted, which is retained by a movable spring giving flexibility to it; the pencil carrier slides in a tube, in which is held, by means of a ring, a helical spring carrying a rod, one end of which is fitted in the head of the pencil carrier. A collar is provided with a screw, serving to regulate the course of the pencil; the tube itself carries a pencil carrier, in which the pencil is placed. The pencil or lead is held by a screw. It will be understood that by these combinations the pencil will sharply and lightly puncture.

In order to give greater facility in the movement of the apparatus a bridle is jointed to the points; that is to say, to its point of contact with the electro retoucher and to its connection with the suspension spring. There is a regulating screw on the armature provided with a spring for obtaining or producing by its vibration the rapid puncturing movement. The pencil carrier may be balanced in a tube having at its end a tail piece, against the bend of which a projecting piece fitted to the end of the armature strikes. By this means the pencil oscillates from top to bottom to give strokes instead of dots or punches.

A small spring is placed inside the tube and bears on the pencil carrier to push the latter upwards when the armature goes towards the bottom. The pencil carrier oscillates on a ring traversed by a pivot.

The invention may also be applied as a tool for engravers.

Improvements in and Relating to the Art of Obtaining by Photography Definite Photographs to be Used in the Production of Typographic Blocks and in the Art of Photolithography and Like Arts. By Messrs. Brown, Barnes, and Bell, of Liverpool.

Our invention has for its object to produce definite photographs broken up into dots, lines, or grains, so that they can be used in the production of typographic blocks by the art of photo-etching and like arts, and can also be used in the art of photolithography and like arts.

In the practice of our invention we proceed as follows:—We take what is known as a photographic transparency of the object or picture; we prefer that this transparency shall be as clear a transparency as possible when seen by transmitted light, and such a transparency can be obtained by processes well known in the art of photography. Having obtained such transparency we place the same upon a lined or hatched background, such as a sheet of white paper, having a lined or grained surface, or a stippled cross hatched or like surface printed or drawn thereon. Any material having such a lined or stippled surface, or effect, or variety of effect, may be used as the background for the transparency. The lining, graining, or stippling of the background may also be varied to suit the picture or object and its surroundings, so that portions of the background may be lined and portions stippled. Having so backed the transparency when viewed by reflected light, the picture of the object can be fairly seen broken up into dots, lines, or grains of the backing showing through the half-tones and clear parts of the transparent picture when viewed by reflected light. In attaching or fixing on the face of such transparent photographs the lined, grained, or stippled surfaces, or backing before described, we do not always confine ourselves to a single sheet of the said surface or backing containing one design only, but we sometimes make combinations by placing in various parts of the transparent photograph suitably cut-out portions of various and differing sheets of lined, dotted, or stippled material, so as to produce a varied and harmonious variety of background suitable to the subject under manipulation. Again, in preparing a suitable backing to combine with the transparent photograph we prepare the backing by hand, or by mechanical manipulation in an artistic manner best suited to the subject or object. Having so prepared and backed the transparency, we take from the transparency so prepared and backed a definite photograph on paper, glass, gelatine, or other sensitised material. This definite photograph has the photograph of the transparency broken up into lines, dots, or grains by the backing. The definite photograph is thus in a condition to be used in the production of typographic blocks by the art of photo-etching and the like arts, and is also suitable to be used in the art of photolithography and like arts.

Another method of producing a definite broken up or divided photograph, having dots, lines, or grains according to our invention, consists in covering the sensitive plate in the camera with a material such as net work, or with a photograph on glass, or other transparent medium, of lines, grains, or stipples, or cross hatched lines, fine or coarse according to the nature of the result required. The photograph on the sensitive plate will then be broken up into the dots, lines, or grains which are photographed simultaneously with the object on the sensitive plate. We thus produce direct a definite photograph broken up and divided into dots, lines, or grains, and in the condition to be used in the production of typographic blocks by the art of photo-etching and the like arts, and also suitable to be used in the art of photolithography and like arts. When required we complete such photograph by hand manipulation, removing or adding dark or light portions, after the manner known in the art of photography as "retouching."

By another method, according to our invention, to produce a typographic block we proceed as follows:—We take a transparent photograph of the picture or object, and we take a transparent photograph of grains, lines, or stipples; and we prepare a plate, or block of zinc, or other suitable metal with bitumen, or other substance that will give a sensitive surface to the zinc or other metal. We then place the photograph of the picture or object and the photograph of the lines, dots, or stipples before spoken of over the sensitised zinc or other metal, and print by light in the usual way, and thus we produce the picture in dots, grains, or lines upon the surface of the zinc or other metal. We then develope the picture, and subject the plate or block to the process of photo-etching in the usual way.

Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, what we claim is—

First. The method substantially as herein set forth of producing from half-tone pictures and photographs, photographs to be used in the production of printing surfaces.

Second. The method substantially as herein set forth of producing in the camera and direct from an object photographs to be used in the production of printing surfaces.

Third. The method substantially as herein set forth of producing photographs upon sensitised surfaces of metal, such as zinc, to be used in the production of printing surfaces.

Rotary Stands for Exhibiting Photographs, &c. A communication by C. A. Schmidt, New York, U.S.A.

The object of this invention is to provide a new and improved rotary sample stand, for exhibiting samples of embroidery, photographs, pictures, or any other articles.

The apparatus consists of a reel-shaped frame, constructed of a pair of discs fixed to the ends of a tubular body and tied together by rods, the said frame being mounted to rotate on a verticle spindle, rising from a suitable foot into the tubular body of the rotary frame. Between the top and bottom discs of this rotary frame skeleton frames or wings suited for holding the photograph or other article to be exhibited are loosely pivoted by their upper and lower inner corners, the said pivots being received in corresponding sockets near the edges of the discs. The said frames are easily removable from the central frame, and the latter may be made without the central tubular body above referred to, the lower disc turning on the spindle, and the upper disc having a downwardly projecting central pivot, which is received in a corresponding socket in the top end of the spindle or standard.

The central frame in which the wings are mounted, and from which they stand out on all sides, can be rotated by a clock-train contained in a casing beneath the central frame and gearing therewith, or by any other suitable motor or by hand. A spring is mounted on any fixed support so as to project in the way of the wings or frames, so that when the stand is rotated the outer end of each wing or frame will strike against said spring and be thereby detained so that the sample upon the face of the wing can be distinctly seen. Or a U-shaped spring may be provided having small rollers at its ends which project in the path of the lower edges of the wings or frames, said spring being fixed to the standard beneath the rotary part of the frame and having its vertical shanks passing through guides in fixed bracket arms.

If the frame be turned around rapidly, the centrifugal force will swing the wings outward, and their lower edges will strike the rollers on the ends of the spring and will press the latter downward, thus permitting the wings to pass; but if any two wings are to be held open when the frame does not revolve, the rollers hold the wings.

Or a spring wire coiled to increase its elasticity and having its ends secured to the standard is bent to a semicircular form, and so placed as to press against the lower edges of the wings and hold them in whatever position they may be placed, the friction not, however, being sufficient to prevent the revolving of the rotary frame. Or a flat ring or segment of a ring is applied in the same position, and is carried on fixed arms by sockets sliding on the upwardly turned ends of the said arms, and is pressed up by coiled springs upon said arms.

The construction can be further modified in various different ways, but in all cases the rotary frame carrying the wings is combined with a spring for holding one or more wings open.

Samples of embroidery, upholstery goods, knitted goods, dry goods, hardware, cutlery, &c., can be held on the wings by suitable bands, or can be cemented to the same. The rotary frame can carry any desired number of wings according to the size of the apparatus.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
May 20	Bolton Club	The Studio, Chancery-lane.
„ 21	Photographic Club	Anderton's Hotel, Fleet-street.
„ 22	London and Provincial	Masons' Hall, Basinghall-street.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The ordinary monthly meeting of this Society was held on Tuesday evening last, the 13th inst., in the Gallery of the Society of Water Colour Painters, 5a., Pall Mall East,—Mr. James Glaisher, F.R.S., in the chair. The summer exhibition of the Society of Water Colour Painters was on view.

The Chairman, in opening the meeting, said a few words on the sad death of Mr. H. Baden Pritchard, who had been a Vice-President of the Society. He had deeply regretted the death of the Rev. F. F. Statham, who had for so long been President of the South London Photographic Society, and had during all that time done what he could to advance the affairs of that society: but now he had received a shock which he could not describe. The other day he had opened a letter and had found in it simply the words "Baden Pritchard is no more!" For twenty years Mr. Pritchard had been an excellent member of the Photographic Society of Great Britain. He had, moreover, been a member of the Council and a Vice-President. Few men, he believed, had gathered around them such a circle of friends as Mr. Pritchard had done. His death would be deeply regretted by all, and all would, he was sure, join in the expression of sympathy to be conveyed to his widow in a letter of condolence from the Society.

Mr. A. Cowan suggested that a formal tribute be sent by the Society in the shape of a wreath to be placed in Mr. Pritchard's grave.

Mr. W. S. Bird seconded the motion, which was carried unanimously.

The Chairman then called on Mr. John Spiller, F.C.S., to read his paper, entitled *Observations on Fading.*

Mr. Spiller said that so much had been already written on the subject that it might appear superfluous to touch upon it again; but the supreme importance of the matter, together with the fact that the subject had been reopened by the reading of a paper by Mr. E. Dunmore before the South London Photographic Society, must be his justification. The cause of the fading of silver prints was pretty well known now by photographers, and, as a rule, due care was taken to use fresh hypo., to thoroughly wash, to use a neutral or alkaline toning bath, and to avoid weak negatives. But the photographer, having seen to all this, was still at the mercy of the paper-makers; for he had to mount his prints either on boards or (sometimes) in albums, and what use was it to remove all hypo. from his prints if he proceeded to mount them on boards with this very substance in them? Sixteen years ago he had pointed out the effect of hypo. on mounts. He had shown that cardboard was seldom or never free from that substance, and a mild appeal was made to paper-makers to abstain from using this salt as an "antichlor." Now that the subject had again come to the front, he had been making experiments and collecting the experience of paper-makers. He had found that hypo. was still present in cards of recent make, and that the use of hypo. as an antichlor was admitted by paper-makers. Experiments were, however, being made on improved methods, which would, he hoped, result in the introduction of a new system likely to be of benefit to photographers. It was possible that a paper might be produced requiring the use of no antichlor. There had been exhibited at a recent meeting of the Chemical Society a paper made by the disintegration of wood at a great pressure, and these specimens looked like the right article and required no antichlor. At the same meeting a large series of sulphites and bisulphites were exhibited which had been used in experiments. He had a set of samples of these chemicals with him. He had been told that the wood pulp could be moved with an equal quantity of rag pulp to produce the finest quality of paper, without any necessity for the use of hypo. If this were so, we were out of our difficulties. There had been a demand of late for cheap mounting-boards, and of course those who used these could not expect much. A patent had been taken out some time ago for neutralising the chlorine left in paper with anti-chloride of lime. In looking back, however, as far as 1844, he found a claim made for the same invention. It was a misfortune for photographers that the process had not been sufficiently perfected to allow of its general adoption at that time. He had tried the comparative effects of sulphite and of hyposulphite of soda on silver prints by immersion of them in saturated solutions of these two substances, and had found that, whereas the sulphite had no effect, the hypo. produced considerable fading. He had also tested the powers of the two substances to dissolve silver, and had found that, when a few silver coins were placed in solutions of them, a test for silver gave an indication in the case of the hyposulphite in a very short time, but none in the case of the sulphite. This showed how the silver image was effected, and how necessary it was to keep hypo. from it. Where there was a question of sulphite or hyposulphite the starch test was useless to distinguish which was present, as both acted in that case similarly. A very ready means of distinguishing between the two was, however, afforded by the fact that the sulphite discharged the colour of a solution of magenta, whereas the hyposulphite did not. This would be a guide for the paper-makers as to how much of the substance to use. Tinted mounts were to be preferred to pure white, as they were not bleached, and, consequently, were not treated with an antichlor. He was informed that in the south of Germany and in Scotland the paper-makers had given up the use of hypo. as an antichlor. Perhaps the reduced price of sulphites would now incline paper-makers to use them, in which case photographers would by no means grumble.

Mr. E. Dunmore thought that had Mr. Spiller looked further into his (Mr. Dunmore's) paper he would have seen it admitted that a solution of hypo. would cause a print to fade. He contended that whilst the print remained dry no such effect would take place.

Captain Abney said that Mr. Spiller had many years ago gone into another cause of the fading of prints, namely, the effect of acids on an organic salt of silver in them, and had pointed out the advisability of keeping the fixing bath alkaline. He thought that Mr. Spiller had been more on the right tack then than now. He could confirm Mr. Dunmore in his statement that, so long as a print remained dry, hypo. in it would not cause fading.

A. Member said he had made a few such experiments and had come to the conclusion that whereas a weak solution of hypo. would cause fading, a strong solution would not.

Mr. J. Werge had prints which thirty years ago had been most thoroughly washed—first in a mass, and afterwards singly—with tepid water. These were all now as good as when they had been printed.

Mr. J. R. Sawyer had some prints taken thirty years ago on paper sensitised on an eighty-grain bath, toned with hypo. and gold, and most imperfectly washed, but they were now as good as good as ever.

Mr. T. M. Brownrigg remembered printing, twenty-eight years ago, and afterwards immersing, the prints in a saturated solution of hypo. and silver, then treating with gold, and washing very imperfectly. These prints were almost the only permanent ones he had.

Mr. T. Sebastian Davis pointed out that we must distinguish between a pure silver image and one partly converted into gold by toning. He thought that if ther were sufficient gold in the print it would be permanent.

Col. H. Stuart Wortley mentioned a case where several of a batch of prints that had been very imperfectly washed had faded, whilst others of the same batch had retained their colour.

Mr. Spiller, in reply, said that although possibly whilst a print remained quite dry hypo. in it might have no effect; but paper was a very hygroscopic substance, and dampness was sure to occur at times. A great deal might be said concerning the organic compounds of silver in prints. He had tried to remove the albuminate of silver which remained in the whites of a print by the use of sulphite of soda, but had found it did not answer.

The Chairman hoped that the paper-makers might take the hint thrown out to them. He then called on Mr. W. E. Debenham to read his paper on *Illumination of the Dark Room.*

Mr. Debenham said that the preservation of one of our faculties was of great importance, and that there appeared little doubt that in the case of photographers that of sight was being greatly injured by the use of red light. He quoted several authorities to show that red light acted injuriously on the eyes. He was sure that for the greater number of operaters red light was a trying one, and that they would be glad to use a yellow light of similar illuminating power if they thought it as safe as the deep red. When first bromide was used for dry collodion plates it was stated that it was proportionately much more sensitive to yellow rays than iodide, and so strongly had this idea seized on the minds of photographers that when gelatino-bromide plates first came into general use, which was in winter, it was said that their superior sensitiveness was entirely due to their greater proportionate sensitiveness to the yellow light which is common at that time of year. When summer came round this was proved to be a mistake. Captain Abney had stated that by using a small quantity of iodide with a bromide emulsion the sensitiveness to the orange rays was so much reduced that an orange light might be freely used to work the plates in. Dr. Eder stated that the addition of iodide to a bromide emulsion increased the sensitiveness to the yellow and green rays. These statements appeared almost exactly opposed to each other. He (Mr. Debenham) had a set of ribands representing as nearly as might be the colours of the spectrum. Emulsions had been made containing—first, pure bromide; second, bromide with five per cent. of iodide; and, third, bromide with ten per cent. of iodide. The ribands were photographed with plates prepared with these three emulsions, and it was impossible to tell the one from the other; but in all cases the red gave more photographic effect than the yellow, so that, were one to use reflected light from such surfaces as a dark-room illuminant, we should choose the yellow colour by preference. He had at one of the technical meetings shown a lantern with four slides, having different coloured media in them. The two most contrasted consisted of two thicknesses of ruby and two thicknesses of yellow and one of greenish glass. The latter had given the most agreeable light, whilst it gave by far the least photographic effect. Captain Abney had, again, brought forward the question, stating that red gave a better result than yellow, selecting as types the glass known as "stained-red," and the paper known as "canary medium." Stained-red has the peculiarity that it is formed by the piling up of a yellow colour. If stained-yellow be piled up it becomes, with a sufficient thickness, red; but the spectroscope still shows the yellow. In the experiments of Captain Abney there appeared to have been an oversight. The trials for illuminating power were made with a small lantern. Now, with clear glass we may reduce the aperture without reducing the light, whereas with a diffusing medium we may not. The trials for the photographic power should, therefore, be made at the same distance from the light as those for the illuminating power; but this had not been done. Another curious thing is that Captain Abney should have found so much less photographic action with stained-red than with yellow, his (Mr. Debenham's) experiments showing the very reverse. When plates were exposed under canary medium, stained-red, and ruby glass, there was the smallest photographic effect with the first, and the greatest with the last. Captain Abney had further stated that the addition of green glass to yellow cut off no rays but such as were harmless. Now, green glass cut off both ends of the spectrum, but let the yellow through freely. It was thus possible to get a yellow light instead of the red, which would arise from accumulating yellow glasses, at the same time some rays of active power were cut off. Captain Abney had recommended stained-red with cobalt. A lantern fitted with this and one fitted with stained-red and green were shown. The latter let pass far most light, whilst the former gave by far the strongest photographic action. This was demonstrated by the development of a plate at the meeting. An arrangement was then shown whereby a comparatively safe *white* light could be got by reflecting on to a diffusing screen red and green light. At a reading distance from this only the faintest image was got on a sensitive plate by one minute's exposure. Another thing in favour of a yellow light was that it suited better the yellowish-green colour of the plates, so that the illumination tests, had they been made with marked plates instead of with matter printed on a white sheet, would have allowed the balance to be still further in favour of the yellow light than it was. He (Mr. Debenham) in summarising his remarks, said he considered that he had established—First: That the great difference in relative sensibility to different colours stated to exist in the two substances (bromide of silver in gelatine and iodide of silver as in a wet plate) does not exist.—Second: That as a consequence the difference said to be required in the colour of the light in which these two are to be worked is not necessary.—Third: That yellow light gives more luminosity in proportion to its photographic effect than does real red light.—Fourth: That stained red glass owes its power of passing luminous rays to the fact that it is an accumulation of yellow colour.—Fifth: That green glass cuts off both ends of the spectrum, and therefore, in addition to rendering a light colour, is a considerable protection.—Sixth: That green glass used as a supplement to red allows more illumination to pass than cobalt so used, and has much more strongly protective effect.

Mr. Sebastian Davis moved that the discussion on Mr. Debenham's paper be postponed till the next meeting.

The Chairman read a communication to the effect that the Art Union of Surrey would hold an exhibition in Guildford, in June, and that photographs of antiquities, &c., of Surrey, would be eligible for admission.

It was stated that Mr. Samuel H. R. Salmon had been elected a member.

Mr. Spiller announced that the funeral of Mr. H. B. Pritchard would take place at Abney Park Cemetery, on Thursday, the 15th instant.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 8th instant, the chair was occupied by Mr. A. Haddon.

Mr. A. L. Henderson produced some developing solution made three years ago; also a plate now developed with some of the same liquid. There was plenty of intensity, and the fact that the mixture had not lost its developing power he attributed to his having added some bromine water to the usual pyro., ammonia, and bromide.

Mr. A. Mackie showed a contrivance for releasing a camera shutter, in which the ball and tube used were filled with water instead of air, as in Cadett's pneumatic arrangement.

The Chairman then called upon Mr. C. Darker to give the *Demonstrations of some of the Phenomena of Light*, for which the evening had been reserved.

Messrs. C. and T. Darker showed, by means of their oxyhydrogen lantern, a variety of experiments illustrating the characteristics of light, accompanied with appropriate explanations. Touching upon the corpuscula and undulatory theories of Newton and Huyghens, the speed of light was next referred to, as calculated by Reaumur from the eclipses of Jupiter; and then the question of the time taken by the optic nerves to convey impressions to the brain was considered. Several demonstrations were made of the effect of rapid motion in causing objects to assume an appearance not actually representing them. Two sheets of perforated metal being revolved, in the manner of a chromatrope, when the speed became high gave the effect of rays darting straight out from a central point. The photodrome was next brought into play, and light having been thrown at regular intervals upon a revolving wheel the spokes of the wheel appeared to be at rest. The identity of the angles of incidence and reflection of light was demonstrated by a beam passing through a smoky atmosphere, and the application of the reflection to record the feeble motion of a magnetic needle employed in long telegraphic lines was shown. Some very beautiful effects were thrown upon the screen by the lantern kaleidoscope of Messrs. Darker, very striking patterns being produced by apparently unlikely subjects. The alteration in light when reflected from a pile of glass plates was next discussed, and the effect of particular states of the atmosphere in inducing polarisation was touched upon and illustrated by a beam of light thrown into a column of water rendered cloudy by a little mastic. A display of objects in the lantern polariscope concluded the demonstration.

After a few observations from Mr. C. Ray Woods, a hearty vote of thanks was accorded to Messrs. Darker.

The next lecturette will be given on the 12th of June, by Mr. W. Coles, on *Altering the Density of Gelatine Negatives.*

EDINBURGH PHOTOGRAPHIC SOCIETY.

The seventh meeting of the current session was held in 5, St. Andrew square, on Wednesday evening, the 7th inst.,—Mr. William Neilson, President, in the chair.

The minutes of the previous meeting having been passed, Messrs. E. Park, James Melville, Robert Gray, and J. Wilson Stewart were admitted ordinary members of the Society.

The Secretary read the following revision of laws as re-arranged by the Council. These are to be discussed at the next meeting:—

1. The office-bearers of the Society shall be a President, two Vice-Presidents, a Secretary, Treasurer, and Curator—to be elected annually, at the first meeting of each session, and all of whom may be re-elected.

2. The Council shall consist of office-bearers and twelve councillors, five of whom shall form a quorum at all meetings of the Council. Four members of the Council shall retire annually by rotation. The Council shall have power to fill up any vacancy in their number during the current year.

3. The Council shall make all necessary arrangements connected with the business and general management of the Society, including its funds; but it shall not be entitled to spend more than ten pounds without special authority being obtained from the Society to do so.

4. The last Council meeting of the session shall be held sixteen days previous to the annual meeting, when the Secretary and Treasurer shall submit their reports.

5. The annual meeting shall be held on the first Wednesday in November.

6. Special meetings of the Society may be called by the Council, or by the President, on his receiving a requisition to that effect signed by ten ordinary members.

7. Applicants for admission as members must be proposed by a member at a meeting, and at a subsequent meeting shall be balloted for, one black ball in five being sufficient to exclude. This law shall also apply to the election of corresponding and honorary members, but these shall not be liable to any contribution to its funds.

8. On admission members shall pay five shillings each as subscription for the year then current. They shall not exercise the privilege of membership until their subscriptions are paid; and the annual subscriptions shall be payable on the first Wednesday of November in each year. Should a member be in arrear for a period of two years he shall thereby cease to be a member.

9. The proposer of a new member shall be considered responsible for the first subscription.

10. The Secretary shall call Council meetings after consultation with the President, and he shall give three days' notice to members. This law shall not apply to cases of emergency.

11. The Treasurer shall keep an account current with a chartered bank in his own name; but when the Society's funds in his hands exceed thirty pounds the surplus shall be lodged in the bank, on deposit receipt, in the joint names of the President and Treasurer as such.

12. The Treasurer's accounts shall, at the close of each session, be examined by the Auditor, and along with his report thereon shall be submitted to the Society at the annual meeting, along with a report by the Council on the business during the previous session.

13. Members may propose a motion or law at a meeting of the Society. The said motion or law shall be printed in the billet calling the next meeting, at which it will be discussed; the said motion or law to be approved by at least two-thirds of the members present at such meeting.

14. Twelve ordinary members shall form a quorum at all meetings of the Society.

Order of Business at all Meetings.—1. Chair taken. 2. Minutes of preceding meeting read and discussed. 3. Admission of new members. 4. Notices and discussion of motions. 5. Other private business. 6. Reading of papers and discussion. 7. Questions or other public business discussed. 8. Exhibition of pictures, apparatus, &c.

Mr. G. G. MITCHELL read a paper, entitled *Photographers and Sitters* [see page 313], for which he received a vote of thanks, on the motion of Mr. Tunny.

Mr. JOHN ANNAN exhibited a large number of landscapes by Mr. Andrew Pringle, Mr. Hay, the late Mr. Black, and others, both amateur and professional. He (Mr. Annan) had collected several sets, each representing the same subject, but by different hands, and was thus enabled to show great diversity of treatment. From the same point of view, and on the same-sized plate, one man produced a bold, massive composition, while another (perhaps through using a wider-angled lens) showed a poor, flat, insignificant result. Another set showed the great diversity of results from a very slight modification of the point of sight; while another set showed prints from the same negative, but cut in different sizes and shapes. In all these examples there was little difficulty in picking out one that stood out distinctly superior to the others, and Mr. Annan pointed out the reasons why, and showed how others had failed. The exhibition possessed high educational value, but without the illustrations his remarks lose their force.

The Chairman, Messrs. Matheson, Brebner, M'Kean, and others congratulated the meeting on the great treat Mr. Annan had afforded them; and a vote of thanks was awarded to him, and to Messrs. Hay and Pringle, by acclamation.

Packets of hydrokinone were distributed among the members willing to experiment with it and state the results at the next meeting.

A set of photographs of the characters in the Passion Play at Ober-Ammergau was exhibited by Mr. G. G. Mitchell, and excited considerable interest.

On the motion of Mr. Thomas Wardale, it was decided to reappoint the Picnic Committee of last year.

A vote of thanks to the Chairman terminated the proceedings.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE ordinary monthly meeting of this Society was held in the Masonic Hall on Tuesday, the 6th instant,—Mr. Councillor Firth in the chair.

A very numerous attendance of members and friends assembled in anticipation of seeing the work of the first trip of the season, which took place on Thursday, the 24th ult. Haddon Hall and Meadows was again selected for the subject of our dry plate and camera campaign, and the force mustered for the "out" was one that any intelligent or scientific person might spend a very pleasant day amongst. There was a four-in-hand coach filled inside and out, and several private conveyances besides.

The day was misty and damp in the early part, and the trees were in some places covered with hoar frost; but as the party went on their journey and the Sun went on his, light and warmth increased, and with them the zeal of some of the members became almost uncontrollable, as they felt disposed to try a plate or two long before they got to their journey's end.

After passing through Bakewell, and making arrangements for a substantial wet plate each, to clear and fix when the daylight was exhausted, Haddon was reached about 11 o'clock. The weather for the first hour was not bright, but cloudy, and the splendid old Hall was overshadowed, so that many of the first pictures of the venerable pile and its surroundings, taken from the meadows, were wanting in contrast; with the exception of one taken by the President, Mr. Firth, who waited and was favoured with a gleam of sunshine which made his picture a brilliant and charming rendering of the subject, with the river, field, and bridge in the foreground, and the massive trees and the well-known castellated wall of the Hall against the sky.

Mr. W. Dakin, with his new outfit of 10×8 camera, by Hare, and various lenses by Dallmeyer to suit, used them as only one long connected with the art could be expected to do, and produced some charming pictures of the old place—one, in particular, of Dorothy Vernon steps, which was very original in selection and remarkably well-timed in exposure, considering the very shady corner the steps stand in.

Mr. J. Taylor, the Hon. Secretary, succeeded in adding to his already valuable and choice selection of Haddon pictures some splendid 12×10 views from new and picturesque positions.

Mr. Seaman, of Chesterfield, worked two cameras, both in and out of the Hall, with unflagging enthusiasm all day, being the first to arrive and the last to leave, taking home with him a rich lot of pictures, both in selection of subject and quality of manipulation.

Mr. H. Rawson, in his usual careful manner, selected a few choice bits as stereos, and half-plate pictures. W. B. Hatfield exposed eleven plates on such positions as were absent from his collection of Haddon, and succeeded in winning in the contest for the best picture, with a whole-plate representation of the banqueting hall interior. Mr. Wood showed a lot of very good pictures—$7\frac{1}{2} \times 5$. Mr. Hayball also succeeded in making up a nice and varied selection by availing himself of the lady figures, which were more for studies than representations of the place.

Mr. Milward, a careful amateur, who has long had in his possession pictures of Haddon Hall which have been much admired at our exhibitions, made some good additions to his stock. Mr. Foxen—a quiet, plodding worker in the art—found many subjects suitable to his way of producing pictures, he having a preference for those compact "bits" he can enlarge.

On this trip there was a good attendance of new members, all amateurs—namely, Messrs. Gilley, Johnson, Pearse, Hibbert, Mottersham, and others—most of these producing something which repaid them. In all there were seventeen cameras at work, and 112 plates were exposed, of various sizes, during the day. There were fifty-six finished pictures shown at the meeting.

The next trip will be to Dovedale, on Thursday next, the 22nd instant. The subject for the competition picture for the forthcoming meeting is *A Rustic Bridge.* Two prizes will be given.

Mr. J. Charlesworth was elected a member.

HALIFAX PHOTOGRAPHIC CLUB.

THE usual monthly meeting was held on Wednesday, the 7th instant,—the Rev. W. E. Hancock, M.A., Vice-President, in the chair.

Mr. THOMAS BIRTWHISTLE, the President, gave a practical demonstration of the platinotype process, developing a large number of prints before the audience. The simplicity of all the operations and the beauty of the results were highly appreciated by all. The majority of the members, however, did not consider the new sepia tint an unqualified success.

The CHAIRMAN asked Mr. W. Clement Williams if he still held the same high opinion of single lenses for landscape purposes.

Mr. WILLIAMS always used them when practicable, and preferred one of the longest possible focus. He did not think any modern single lens that had come under his notice gave as good definition, depth, and brilliancy, or as pleasing perspective, as that afforded by the old-fashioned and bulky form. Its weight and size were certainly a great drawback; but the better quality of results was to him an ample compensation for the other "pains and penalties" connected with it.

The annual trip of the Club was arranged to be held on Midsummer Day next. Bolton Woods was the place selected for operations, when a number of prizes will be offered for competition.

A hearty vote of thanks to Mr. Birtwhistle for his very able and interesting demonstration brought the proceedings to a close.

BOLTON PHOTOGRAPHIC SOCIETY.

ON Wednesday evening, the 30th ult., the third annual *soirée* of the members of the Bolton Photographic Society was held in the Baths Assembly Rooms, when there was a large attendance of members and their friends. Round the room were ranged tables filled with specimens of the photographic art, the work of the members, the productions being highly creditable to amateur effort, and would certainly not disgrace the work of the accomplished professional artist.

Prominent amongst the specimens exhibited were those of our townsman, Mr. T. Parkinson—a hundred in number—which claimed, and justly so, a large share of attention. Amongst the finest of these views was one of the interior of Mytton Hall, the residence of John Hick, Esq., J.P., the esteemed President of the Society. Another was a good view, taken by electricity some few years ago, of a group of the members of the Microscopic Society in the Town Hall. Other specimens were a large carbon *plaque*, on opal, of the Rev. Canon Powell, and mounted in plush; a group of the family of Major Cross Ormrod, taken at Barnacre, the family seat at Scorton; a carbon enlargement of the Parish Church interior; view of the Germania Monument, on the banks of the Rhine; an interior of Holy Trinity Church, in carbon; and the interior of the Botanic Gardens, Southport.

Some exceedingly good specimens of photography were shown by Mr. C. K. Dalton, Bridge-street, including a view of Pandy Mills, near Bettws-y-Coed; an instantaneous photograph, entitled *A Cloudy Day at New Brighton;* another instantaneous view of Bridge-street, besides a scene in Ashworth Glen, in platinotype. Mr. R. Mercer, Market-street, had some beautiful views, also in platinotype, chiefly of Smithills Hall, which were greatly admired.

Mr. John W. Hawksworth, the energetic Secretary of the Society, displayed a few good specimens, recently taken, of Furness Abbey, as well as a large view of the Fever Hospital, with the Sanitary Committee posed in the foreground.

J. R. Bridson, Esq., J.P., Belle Isle, one of the Vice-Presidents, displayed some twenty views of Windermere scenery, as beautiful in execution and production as the exquisite subjects deserved; and Professor Heaton displayed some pretty views of Swiss scenery.

Mr. Wm. Banks, Corporation-street, had a few good photographs—one of the *Switching Room*, in connection with the Telephonic Exchange at Manchester, being particularly good. He also displayed a quantity of apparatus, &c.

Mr. W. Laithwaite had a few good views of Turton Tower, the Jumbles, &c. Mr. E. N. Ashworth, Turton, had some fine photographic pictures of Scotch and Cumberland scenery and Haddon Hall, with Dorothy Vernon's door—dear to the lovers of romance. Mr. B. Abbatt and Mr. J. S. Jackson were also exhibitors, their specimens, though few, being good; and the Rev. J. W. Cundy, M.A., had some excellent photographs of the Italian alps.

Among the outside specimens may be mentioned three excellent sea views from the Autotype Company, London, and a number of splendid photographs produced by Mr. J. B. Wood, a member of the Manchester Photographic Society, who kindly officiated as descriptive lecturer in the place of Mr. Galloway, who had on previous occasions amused the audience by his anecdotes, &c. In Mr. Wood was found a very able substitute, as he kept the company in roars of laughter by his terse and racy descriptions and tales.

Mr. J. R. Bridson, one of the Vice-Presidents, acted as chairman in the absence of Mr. John Hick. He congratulated the Society upon its proficiency, and heartily wished the members success.

Mr. Hawksworth, Secretary, read the report, which was satisfactory, showing that since last season twenty new members had joined the Society.

The Bolton glee party (Messrs. Houghton, Howarth, Warburton, and Walls) were in attendance, with Mr. J. Bentley at the pianoforte, the proceedings being enlivened by their united efforts.

Correspondence.

THE NEW DEVELOPER.

To the EDITORS.

GENTLEMEN,—Your article in the Journal of April 25, on *A New Developer*, was very interesting to me, as doubtless to most of your readers, for it threw new light on the use of sodic sulphite, and especially in connection with carbonate of soda.

I have long preferred the carbonate of soda developer to the ammonia, but have met with sundry difficulties in producing *uniformly* negatives of high class. Upon reading your article I at once developed a Swan "ordinary" according to your formula, and obtained in ninety minutes a fully developed negative *slightly* veiled. I then gave some $7\frac{1}{2} \times 5$ Swan's "ordinary" and Autotype "challenge" slow plates a five seconds' exposure in fair light, with No. 5 stop (*the smallest*) Ross's portable symmetrical, and developed with—

Pyro.	4 grains,
Sodic sulphite	30 ,,
Water	1 ounce,
Anhydrous carbonate of soda	40 grains,
Water	1 ounce.

I flooded the plates with water for (say) a minute, then applied one ounce of pyro. and sodic sulphite; I kept it moving for, perhaps, half a minute to a minute, and then added one ounce of the carbonate of soda. The image developed quickly and with ample density, excellent gradation, and beautifully clear shadows; while in colour, gradation, and sparkle it more nearly resembled one of my old iron negatives than anything I have yet obtained with gelatine.

I have also given an exposure of five seconds to one plate and ten seconds to another, and by using a less quantity of the carbonate of soda to the ten-second plate produced two negatives barely if at all distinguishable one from the other.

I prefer the anhydrous soda to the ordinary or even the recrystallised; it seems to give clearer shadows and crisper pictures, and it must be a more definite product than either of the others.

If you have not tried this form of developer, and will take a Swan ordinary plate, give a *short* exposure with a small stop, cut it in half, develope one half with the above and the other with the ordinary ammonia-pyro. developer, I think you will find that the former will give you by far the best negative and with at least one-third less exposure than for ammonia and pyro.

As to the asserted permanent character of the sulpho-pyro. developer: if you will mix (say) enough to develope two or three negatives as per the above formula, develope *one* negative and note the exposure and time of development, then keep the remainder for only one week and give a plate a similar exposure, also cut it in half and develope one half with the week-old mixture and the other with a freshly-made one, you will find that you will hardly get any image at all on the first while the second will be all right.

Have you ever tried precipitated chalk for removing the gloss of varnish for retouching? If not I think upon trial you would prefer it to either ground cuttle-fish, a pumice, or any of the *smeary* messes which are used for that purpose. It gives a *very fine* matt surface without any scratches.—I am, yours, &c., W. BASSANO.

Haden Cross, Old Hill, May 12, 1884.

MOUNTING PRINTS.—PRESERVING THE MOUNTING SOLUTION.

To the EDITORS.

GENTLEMEN,—I may first say I know nothing of chemistry, and only work in a practical way as taught by the skill and experience of others. There may, therefore, be something wrong in what I recommend; but I only give my own experience, to be tested by others possessing more knowledge than myself.

I mount my prints with the solution of gelatine and alcohol given in your ALMANAC. I found that here, in India, it went bad in a week. I have been in the habit of using boro-glyceride to keep meat and milk fresh, and I find one teaspoonful of boro-glyceride will keep a pint of milk sweet for quite a week. I therefore, in making up my mounting solution, put a small egg-spoonful into the solution of about three ounces. I made up a bottle of solution in October, 1883, and when I had occasion to use it a few days ago it was perfectly good and sweet.

Perhaps this boro-glyceride may be a useful addition, not only to the mounting solution, but also to albumenised paper, and may be to emulsion.—I am, yours, &c., E. P. R.

Mahablishmar, Bombay, April 23, 1884.

DEVELOPING-ROOM ILLUMINATION.

To the EDITORS.

GENTLEMEN,—Your correction was technically right about there being more colour absorption by two sheets instead of one of the same glass, especially feebly-coloured samples. I stated there was some. I was writing briefly for practical purposes, and in a general sense the rule of action was correct. From recent experience I should be sorry hereafter to use a screen which did not let more and cooler light through than one sheet of ruby glass; but this can only be done by selecting two screens upon scientific principles—translucent and not transparent.

What does Mr. W. E. Debenham mean by entitling his paper to the Photographic Society "Illumination of the Dark Room?" If the room be dark, how can it be illuminated? The same question may be put to Mr. A. Pringle, who heads his articles "The 'Happy Medium,' or Dark-Room Illumination." If one thing more than another makes a medium unhappy it is the illumination of the dark room.—I am, yours, &c.,

London, May 9, 1884. W. H. HARRISON.

HYPO. IN PHOTOGRAPHIC MOUNTS.

To the EDITORS.

GENTLEMEN,—Having noted in your issue of April 25th Dr. Nicol's remarks regarding Mr. A. Duthie's statement as to the presence of hyposulphite in mounts, and having examined some of the same mounts, I beg leave to confirm Mr. Duthie, my tests having shown undoubtedly the presence of that substance in distinct traces.

The tests were conducted very carefully in my own laboratory. Every precaution which the science of chemistry could suggest was used, the mounts being digested in *boiled* distilled water to prevent oxidation. One of the tests employed, according to Dr. E. J. Reynolds (*Chemical News*, vii., 283), detects hypo. when present in the minutest traces—even $\frac{1}{300000}$th part.

If Dr. Nicol will state the test which apparently satisfies himself I shall be happy to use it, and state my results.—I am, yours, &c.,

Glasgow, May 12, 1884. JAMES MUTER.

THE SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

To the EDITORS.

GENTLEMEN,—It may interest you to learn that we have just organised a new amateur photographic society for this city and vicinity, of which I am President.

No society here proposes to do or does what we intend to perform. We have several wealthy amateurs interested, and propose to fit up a hall with suitable appliances for photographic experiments, in order that practical demonstrations can be given at meetings.

We also wish to establish a system of exchange of pictures, apparatus, and negatives with foreign societies, and open a correspondence with the same. We expect to have a very complete photographic library replete with copies of the latest English and American patents and current literature.

Should you or any of your friends visit this country be sure and give us a call.—I am, yours, &c., F. C. BEACH.

361, *Broadway, New York.* *President, Society of Amateur Photographers.*

Notes and Queries.

W. M. H. writes:—"Can anyone inform me as to the best means of improving a studio where the side lights have been blocked out by a wall higher than the said studio, and situated at four yards' distance? Would painting the said wall a light colour do? The sun, it must be remembered, shines all day on the wall. Would anyone who has been in the same 'fix' give me the result of his experience, which will be thankfully received."

"THERE appeared in your Journal, some time since, a letter from Mr. Smith recommending the use of the 'ferrous oxalate developer,' and great stress was laid on the fact of its keeping qualities. Now, I have given it a fair trial, and am perfectly satisfied with it *as* a developer; but I cannot prevent it forming crystals and turning the sides of the bottle green when kept and allowed to remain where the sun can shine on it to revive it. I have tried it with more or less acid, but it just goes the same, although I have carried out M. Audra's formula to the letter. I shall be glad if Mr. Smith or any other reader of the Journal inform me how to prevent the formation of crystals, and keep the developer up to its strength.—A. HOLT."

"Is there any way by which old collodion can be decolorised? I have some obtained a few years ago for negative work; but which the influx of gelatine plates caused me to abandon. It is now of an exceedingly deep, red colour, and I am desirous of trying the wet collodion process once more, previous to which I wish the collodion restored.—S. R. S." ——In reply: Shake up some zinc filings with the collodion and it is probable that the colour will disappear. But we do not believe that the original sensitiveness of the collodion will ever be restored. If it be required for the preparation of lantern or other transparencies, then its age will prove no drawback to its employment, because, for this purpose, old collodion not unfrequently answers better than new.

"INQUIRER" is making a collection of "men of mark" in photography who have passed away, and asks by what means he can procure a portrait of Mr. Thomas Sutton.——We reply that in 1875, within a few weeks subsequent to the death of that gentleman, we published a sketch of his history illustrated by an admirable portrait, which in the estimation of his friends is one of the best that has ever been taken. To the volume for the year mentioned, and page 211, we refer "Inquirer."

GEO. BARCLAY says:—"I observe, in a report of the proceedings at one of the London photographic societies, that attention was specially directed to the use of a plano-concave lens inserted immediately in front of the sensitive plate as a means of ensuring extreme sharpness up to the edges, even when a lens is employed with full aperture. Will you inform me if such plano-concave lenses can be readily procured, and, if so, where?"——In reply: Lenses of the class referred to are not commercial productions, and to procure one it would be necessary to have it specially made.

"IN practising the collodion transfer process what is the best preparation for the plate to enable the collodion film to leave it readily? I sometimes experience difficulty in stripping, and imagine that it is owing to the intimate adhesion of the collodion to the surface of the glass.—P.P.A."——In reply: The plate may be rubbed over with a five-grain solution of wax in rectified benzole previous to applying the collodion; or it may be briskly rubbed with a calico pad well charged with finely-powdered French chalk. This will ensure successful stripping, provided the transfer paper be good.

"I FIND it rather difficult to follow the description of the instrument for viewing lantern transparencies without a lantern, suggested in your article of the 2nd instant. May I ask, in my own interest and that of my fellow-readers, if you could kindly give rather fuller details, illustrated by a simple sketch or sectional view? This would prove very useful to all those who, like myself, intend to construct it.—B. O. S."——In reply: We shall endeavour before long to place on public exhibition one of the instruments described, with full permission to all to copy or imitate it to any extent desired. We have the satisfaction of knowing that the description we gave has proved in more than one instance sufficient to cause a satisfactory result to be obtained.

"I PROPOSE making a camera to take views about $2\frac{1}{2} \times 2$ (to be afterwards enlarged) with a snap shutter and plates or, if obtainable, films, of such rapidity as to allow of pictures being taken while the camera is held in the hand. My question, therefore, is—'What lens would be the most suitable?' I should prefer one of some depth of focus, so as to dispense, if possible, with the necessity for adjustment. I intend to use a view-meter. I read, some time back, a paper by M. Léon Vidal, in which he spoke highly of some films made by a fellow-countryman of his. Are these obtainable in London (if, indeed, you can identify them from my somewhat vague reference)?—REGD. M. SMITH."——In reply: Let our correspondent employ a portrait lens of the class intended for lockets, and which will usually cover the size of plate intended to be used in this case. If of foreign manufacture the cost will not exceed a sovereign. Should a diaphragm be found necessary, let it be placed as closely as possible to the front lens, in order to diminish the chances of a flare spot being formed in the centre of the picture. We have no practical knowledge of the films of which M. Léon Vidal has spoken; but, for pictures of such small dimensions, we think glass as a means of support will offer advantages superior to flexible films.

Exchange Column.

I will exchange a new victoria camera, with nine lenses; also, a Shew's 5×4 extra-rapid rectilinear lens for anything useful in value.—Address, C. P. GEE, Weymouth.

I have a Solomon's magnesium lamp and a 10×8 wide-angle view lens (Photo. Stores make) for exchange. What offers?—Address, CHAS. TAYLOR, photographer, Chislehurst, Kent.

I will exchange eighty-nine numbers (complete) of Cassell's *Illustrated Dictionary of Mechanics* for a pedestal and balustrade, or other useful studio accessories.—Address, A. J. G., photographer, Honiton.

I will exchange a beautiful double-plated electric machine, equal to new and cost £15, for a good half-plate bellows-body camera with double backs and lens, by a good maker.—Address, G. J. H., Post-Office, Ballincollig, Co. Cork.

I will exchange a Ross's 10×8 rapid symmetrical lens, quite new, used a few times, for a half-plate, same make, or half-plate doublet, must be good; also, wanted a solar enlarging lantern.—Address, J. COLLIS, 8, Stuart Hall, Cardiff.

Wanted, a good 10×8 Kinnear camera in exchange for a cabinet rolling-press, upright rollers, eight inches long, cost £1 4s. six months since, and a mahogany camera to take two on a 5×4 plate; photographs, three stamps.—Address, H. WALKER, 150, College-road, Bradford, Yorks.

I will exchange a four-lens gem camera, which takes twelve on a-quarter plate, dark slide, all in complete order, for a 5×4 or half-plate lens for groups, &c., or a good binocular stereoscopic camera and lenses, with dark slides, or ferrotype plates.—Address, 21, Bartholomew-street, St. Olave's Row, Exeter.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

A. SEYMOUR (Cambs.).—If you copy the cartoons in *Punch*, *carte* size, and publish them, as you propose, you will certainly get yourself into trouble. *Punch* is very jealous of his copyright.

ENTHUSIAST.—We fear you are aspiring to too much. Such pictures are very interesting as local views; but they will have little commercial value out of the district in which they are taken.

R. S. HILL.—In all probability the print was sulphuretted in the fixing bath; hence the cause of its fading so rapidly. Possibly the mountant was acid, and that further accelerated the fading.

IN THE DARK.—If the lens be three and a-half inches focus the plate wi have to be, approximately, that distance from the optical centre when the view is taken. We should recommend you to purchase some cheap work on optics.

R. B. Y.—Your surmise is probably correct—that it was the thunder that caused the emulsion to behave in the way it did. Your experience is by no means exceptional. Thunder has often a marked influence on solutions of gelatine.

B. CLARK.—If you reckon the parts as drachms or ounces, according to your requirements, whether fluid or solid, you will be correct. Heinrich's gelatine may be procured from Messrs. A. and M. Zimmerman, 27, Mincing-lane, E.C.

X. A. B.—The old makes of photographic papers—such as Canson's, Turner's, Whatman's, and others—which were used in the calotype and wax-paper processes, are not to be procured at the present time. Try *Saxe* or *Rives* instead.

J. W. WRIGHT.—If you stop out all the light from the end of the studi you will find a marked improvement in your pictures. It is having so much front light in the room which causes the faces to appear so flat and wanting in rotundity.

WM. J. J.—The process has not been published, nor is it likely to be at present, as those who work it keep the details a secret. It is, however, believed to be a modification of one invented by Mr. Woodbury—the same you refer to at the conclusion of your letter.

A. BRAY.—The want of sharpness in the pictures is clearly due to a movement of the camera during the exposure, possibly caused by the instantaneous shutter. The remedy is to make the shutter run more freely in the groove, or to get a new one on another principle.

A YOUTHFUL EXPERIMENTER.—Unless the pyroxyline be an exceptiona sample, ten grains to the ounce of solvent will be a great deal too much for collodion in the wet process, notwithstanding what you were told by the chemist. Five or six grains is much nearer the mark.

W. H. JAMES.—1. The apparatus is not yet an article of commerce; you will, therefore, have to construct it for yourself from the description given.—2. You will have to substitute another form of shutter. Any shutter that works horizontally instead of vertically will answer.

G. R. FLUDDER.—The instrument is very good, we believe, for the price. Of course it would not be fair to compare it with one costing several times the amount, such as the second you mention. With regard to the shutter: we have had no practical experience with it, so can offer no opinion.

BOS.—The washing out of the delicate half-tints of your carbon prints is due to the tissue being in a too-soluble condition; that is, supposing you have printed sufficiently deep in the first instance. The remedy is either to keep the tissue longer before printing it or to dry it more slowly. Another remedy for this evil is to sensitise the tissue in a stronger bath.

REV. J. B.—The best suggestion we can make is that you get a few practical lessons in lithographic printing from some experienced lithographer. If you understand a little of the practical portion of the work you will find the knowledge of great value in your experiments. Indeed, it is almost imperative that you understand the printing before you commence to experiment.

ECCLESIASTIC.—The "canon's uniform," referred to in the article on *Photography at a Fancy Dress Ball*, is an emendation of the "devil"—the "p. d." of course. We cannot expect him to have an intimate knowledge of things ecclesiastical, but we fail to discover the line of thought by which he connects a "canon" with a "Somerset House porter." We wrote "*curious* uniform," but then we don't write copper-plate.

NUMBER ONE.—Yes; if you dissolve silver in nitric acid you get nitrate o silver. But in dissolving your half-crown you have got nitrate of copper as well as nitrate of silver; hence the cause of the green colour. You appear to be unaware of the fact that the current coin is not pure silver, but an alloy of silver and copper, and therefore should not be employed to make nitrate of silver for photographic purposes. You will find it much better to purchase your nitrate of silver than to manufacture it yourself.

RECEIVED.—A. Conan Doyle, M.B., C.M. In our next.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 21st inst., the subject for discussion will be—*On the Relative Merits of Boiled and Ammonia Emulsions.* Tomorrow (Saturday) the members will have an "outing" to Watford and Grove Mill.

BALLOON SOCIETY OF GREAT BRITAIN.—This Society has made arrangements for holding a number of garden parties during the ensuing season. The first will be held at the Crystal Palace on Saturday, the 31st inst. Photographers who are members of the Society, desirous of being present, may obtain tickets on application to the Secretary.

JOURNAL OF PHOTOGRAPHY.

No. 1255. Vol. XXXI.—MAY 23, 1884.

IODIDE OF SILVER IN EMULSIONS.

In our previous articles we have spoken of the beneficial restraining action which iodide of silver is capable of exercising when present in a sensitive film; and we now wish to demonstrate that a similarly beneficial effect is produced by it during the preparation of the emulsion.

Let us first mix a bromide emulsion in the ordinary manner, observing that it is strictly neutral, and before boiling divide it into two portions, to one of which a few grains—say one grain to each ounce—of iodide of potassium are added, and to the other an equivalent quantity of bromide of potassium. We have now two emulsions containing precisely the same quantities of silver and the same excess of soluble bromide; but differing in that one contains plain silver bromide, the other bromo-iodide. The colour of the latter by transmitted light will be of a deeper and browner red than the other, and it will be found upon boiling the two that the red colour is more persistent in the case of the iodide emulsion. Thus, at the end of half-an-hour's boiling, under whatever conditions that operation may be performed, it is nearly certain that the bromide emulsion will have lost every trace of red or orange by transmitted light; but in all probability the other will still retain a decided orange tint, and will give a film which dries full orange, or even red.

If the boiling be prolonged, and small quantities of each emulsion drawn off at measured intervals for trial, it will be found that not only in the matter of colour is there a marked difference between the two emulsions, but that the character of the image as well as the sensitiveness vary greatly. The image given by the plain bromide will, when a certain stage is reached, commence to grow thinner, the sensitiveness continuing to increase until a point is arrived at where the thinness of the image is so excessive as to render the emulsion useless. This thinning process, in fact, governs the degree of sensitiveness practically attainable. In the case of the bromo-iodide emulsion the process goes on, but the thinning of the image is more gradual and commences at a later point. The rate of increase of sensitiveness is about equal in the two emulsions—if anything slightly more rapid in the case of the plain bromide.

The result of pushing this experiment to its utmost limit—that is to say, of continuing the boiling in each case until the emulsion becomes useless—will be to find that a more sensitive preparation is obtainable with than without iodide. If carried to the extremest limit which will permit of the formation of a developable image, the mixed emulsion will be many times more sensitive than the other; but, confining the experiment within the bounds of practicability—that is, arresting the process before the image ceases to be of a utilisable character—we can get a sensitiveness of 3 : 1 in favour of the iodide. This, of course, involves, as will have been gathered, a longer boiling in the case of the iodide containing emulsion, the function of the latter being to retard the acquisition of sensitiveness and the production of fog and thinness of image, but the action is proportionately feeble in the first case.

That the effect produced is really a restraining action of some sort exercised by the iodide during the process of boiling is, we think, clearly proved by the fact that the addition of the iodide *after* boiling appears to be quite without effect. A plain bromide emulsion mixed and boiled to the verge of fog was divided into two parts, to one of which iodide of potassium was added in the proportions mentioned previously. In spite of the circumstance that this last emulsion would contain a larger proportion of free bromide than the other, not the slightest difference was discoverable between the two. The addition of a portion of a separately-formed and washed iodide of silver emulsion in place of the iodide of potassium produced also negative results; but when this addition was made before boiling the beneficial action of the iodide became evident.

So far we have spoken only of boiled emulsion, as our experiments with neutral mixtures have been confined to that method of preparation; but there is no reason why the same effects should not be obtained when any other method of emulsification, prolonged or otherwise, is adopted. Possibly in any of the precipitation processes the different molecular condition of the iodide of silver may cause a variation in the results, but it would not be difficult to devise a modification of the usual mode of procedure by which the beneficial action might be secured.

Turning now to the method of emulsification with ammonia—we treat the method as a principle without reference to variations of formulæ—we find the presence of iodide even of greater benefit than under the conditions already stated. The beneficial effect in this case, however, is more marked upon the quality of the image, and, of course, through that, indirectly upon the *practical* sensitiveness of the preparation. The ammonia appears to exercise a powerful sensitising action upon the iodide of silver, or, perhaps, more correctly speaking, it confers upon it the power of giving dense images. Something of the same sort may be seen if a drop of dilute ammonia be placed upon a film containing iodide of silver, when, if taken into daylight, that portion of the film will darken rapidly to a dense black.

If a series of comparative experiments similar to those referred to above be conducted in connection with an ammonia emulsion, the same general results will be obtained; but in this case the beneficial action of the iodide becomes more and more apparent (in improvement of the quality of the image) in proportion as the sensitiveness is increased.

Before finishing we may describe the method we adopted in performing the successive trials of the emulsion at different stages. At stated intervals small portions (of one drachm each) of the thin emulsion were drawn off into test tubes, and to each were added two and a-half grains of dry gelatine. When dissolved the drachm of emulsion was spread upon a quarter-plate, allowed to set, plunged into a mixture of two parts of alcohol and one of water for five minutes, then for two minutes more into undiluted alcohol, and finally rinsed over with a third application and dried. By this method a comparatively-small quantity of emulsion suffices for a large number of comparative experiments. The inconvenience of removing the decomposition salts from a large number of distinct emulsions is minimised by treating the films separately; and if care be observed we secure almost absolute identity of treatment in all cases.

In conclusion: let us impress upon our readers that we do not for one moment claim, or wish to appear to claim, that iodide of silver is more rapid than bromide, or even as rapid; but that, by utilising the peculiar restraining action it exercises, the bromide of silver itself may be made more practically sensitive than is the case when it is employed alone.

REVOLVING ADAPTER FOR LENSES.

To obtain results by the quickest and most direct means is one of the characteristics of the age, and it pervades many departments of applied science. In none, perhaps, is this tendency more definitely displayed than in what are so well known as revolving firearms. In microscopic science, too, has the principle of rapid successive action been applied, and with such an acknowledged measure of convenience and success as to have led to its further extension. We here allude to what are so well known as "nosepieces" for objectives, which, at first, double, soon became triple, and are now quadruple, in their scope. The function of these, we may here inform the non-microscopical reader, is to carry, screwed up into position on a rotating plate or adapter, a variety of objectives or powers of varying degrees of strength, which are capable of being brought in succession, and almost by a touch of the finger and thumb, into the axis of the instrument, thus enabling the observer to study any special object under circumstances of quick transition from a low to a high standard of magnifying power. In photographic optics an instance of this successive adaptation is familiar to every reader in the form of the rotating plate of diaphragms.

Taking advantage of the uniformly small sizes in which photographic lenses of great focal range are now constructed, we have for a considerable period had a battery of three lenses of this class screwed side by side on the camera front, the outer two being of similar foci for stereoscopic purposes, and the central one of longer focus for covering the whole area of the plate ($7\frac{1}{2} \times 5$) in that particular camera. This principle of utilising what would otherwise be waste space and saving an extra front to the camera is known to, and adopted by, several of our readers; but of late we have sought to carry this adapting principle much farther for single camera views in contradistinction to binocular photography.

At first we had a row of small lenses of different foci mounted upon a straight strip of wood in which were a series of notches, and into these a catch fell when any lens was brought directly opposite the aperture in the camera front. This answered its purpose well and provided the means of viewing upon the ground glass the scene intended to be depicted under various degrees of amplification, and, of course, with more or less of the subject included. Under ordinary circumstances this could only be effected by the tedious process of unscrewing one lens from the camera and screwing in another; but here it is done with a touch—the lens is pushed to one side, and a click announces that its successor is centered and in its correct position.

Although the system just described has answered the intended purpose in an admirable manner, yet of late we had experienced a desire to try a rotary system in strict analogy with the six-chambered rotating charge-holder of the modern revolver firearm. Premising that the camera is a portable one for 8×5 plates, we have a circular plate of four and a-half inches diameter revolving upon a screw in the centre, like the rotating diaphragm plate, and having five perforations round the margin. In these are screwed four small lenses of a strictly portable class, having equivalent foci varying from three and a-half inches up to twelve inches, together with a fifth lens of larger dimensions and greater rapidity of action for employment with an instantaneous shutter.

The advantage of this method of mounting lenses lies in the extreme rapidity with which any one of the battery can be brought into action at a moment's notice, and the tentative system that can be adopted without loss of time, permitting the effect to be perceived on the ground glass whether the subject be depicted by a long- or short-focus lens.

In fitting a number of lenses in this revolver fashion certain precautions are necessary, but, happily, they are only few. The rotating plate upon which the lenses are screwed must be attached to the rising front of the camera, and the circular aperture in this front must be no larger than the back cell of the lens at the front, while it must taper out rather widely at the back to admit of the transmission of an extremely-oblique ray when a lens of very short focus is employed. Again: the rotating plate upon which the lenses are screwed must be fitted so closely upon the camera front as not to permit of any leakage of light between them. But it would be almost an insult to intelligent photographers to hint that such leakage may be altogether prevented by the insertion of a band of velvet ribbon, such fact being obvious to every reader.

When only three or, at most, four lenses are employed they may be attached to the revolving piece by the usual flanges; but when, owing to their increased number and consequent proximity, there would be no room for them were such flanges adopted, then they must be affixed by other means. The most simple method is to cut an aperture in the wood of a size just capable of admitting the lens and a ring which is inserted from behind and screwed upon the lens mount. True, a flange could be employed in the usual way, having its sides cut away so as to enable the lenses to be brought close together, but the projecting plate of rotating stops would in most cases interfere with this; for, unless these were previously removed from the mount, the latter could not be screwed in its flange on account of the contiguity of the adjoining lens. But no matter by what means the lenses are screwed upon the revolving front it is necessary that there be no projections whatever upon or behind the latter.

The lenses, when brought in rotation precisely opposite the aperture in the camera front, must be retained there until a mark is made on the periphery of the circular revolver, in which a notch is eventually cut. We may add that no one who tries this system of mounting lenses will care to revert to the old and original method of screwing and unscrewing the lenses to suit the varied requirements of the subject about to be photographed.

THE NEW COPYRIGHT BILL.

Once more a new Copyright Bill has been introduced into the House of Commons, read a first time, ordered to be printed, and was issued last week. Whether it will share any better fate than its predecessors—which have been brought forward annually or several years past—time alone will determine.

In its main features the present Bill differs in no material extent from the former ones, most of the principal clauses being retained in their entirety. But some few and by no means unimportant ones have been added—the necessity of which have been suggested by the recent decisions under the old act of 1862—while others have been amended. For instance: in clause 9, which in its meaning is similar to that in former bills, we find the term "author"—upon which the now famous case of Nottage *versus* Jackson broke down—is expunged, and that of "person" used in its place. With this clause is now embodied clause 11 of the former bills, which provides that the copyright in all work executed by an *employé* is to be the property of the employer. This clause also defines the duration of copyright in photographs, which is to be fifty years from the date of publication. As this clause is one of the most comprehensive and important in the Bill we here give it in its entirety:—

9. Every person who, without infringing any copyright, shall lawfully make or have made any photograph which shall not have been published before the commencement of this Act, such person being a British subject, or domiciled in some part of the United Kingdom, at the time when such photograph shall be published, shall have the sole right of copying, reproducing, and multiplying the same for the term of *fifty years*, commencing on the first day of the calendar month in which it shall be published: Provided always (first) that, where in making a photograph a negative is first made, the said right shall belong to the maker of the negative; (secondly) that, where a photographic copy of any work of fine art is made on commission for or by request or permission of the owner of the copyright in that work, the copyright in the copy shall belong to the owner of the copyright in the work copied; (thirdly) that if any person employs another as his assistant, servant, or workman to work for him for salary, wages, or hire, for the purpose of making or assisting in making any photograph, or the negative of any photograph, the copyright in such photograph and negative shall belong to the employer, such employer being a

British subject, or domiciled in some part of the United Kingdom at the time when such photograph shall be published.

Clause 22 is framed expressly to prohibit the importation of pirated works of art and photographs produced abroad, which experience shows to be very necessary. It enacts—or will enact if it become law—that any owner of copyright, if he have reasonable cause to suspect that any parcels of goods being imported contain pirated copies of his work, may make declaration to that effect. Then any such suspected goods will be unpacked and examined by the Custom House officials, and by them detained. Notice of the detention is then to be served on the importer, and if within fourteen days an action in respect to such detention shall not be brought against the owner of the copyright, then all the pirated copies are to be delivered up to him or his agent, and will become his property.

A very important clause in the new Bill is clause 23, which enacts that anyone selling pirated copies of any photograph or work of art is bound to disclose from whom he procured them. The importance of this clause is great, inasmuch as it will enable the actual pirate to be detected and probably brought to justice. This it is next to impossible to do under existing circumstances, unless the evidence be voluntarily given by the seller. Hence, in prosecutions for infringement of copyright, it is no uncommon circumstance for the prosecution to withdraw the case as against the seller, or to ask only for mitigated penalties, upon the consideration that he will give information as to the actual producer of the pirated pictures. Upon refusal to give the necessary information a penalty of five pounds will be incurred. As this clause is entirely new, we give it at length :—

23. Every person who shall import or export, or cause to be imported or exported, into or out of any part of the United Kingdom, or shall exchange, publish, sell, let to hire, exhibit, or distribute, or offer, or hawk, or carry about, or keep for sale, hire, exhibition, or distribution any unlawful copy, repetition, or imitation of any work of fine art, in which or in the design whereof there shall be subsisting copyright, or of any photograph in which there shall be subsisting copyright, or any work of fine art upon or to which any name, initials, monogram, or mark shall have been signed, placed, or affixed in manner prohibited by section twenty of this Act, shall be bound, upon demand in writing delivered to him or left for him at his last known place of abode or business, or at the place of such exchange, publication, sale, exhibition, or distribution, or offering or keeping for sale, exchange, exhibition, or distribution as aforesaid, by the owner of such copyright or other person aggrieved, to give the person requiring the same, or his attorney or agent, within forty-eight hours after such demand, full information in writing of the name and address of the person from whom and of the times when he shall have imported, purchased, or obtained such copy, repetition, or imitation, or such work of fine art, and the number of such copies, repetitions, and imitations which he shall have imported, purchased, or obtained, and also to produce to the person requiring such information, or his attorney or agent, all invoices, books, and other documents relating to the same ; and it shall be lawful for any justice of the peace upon information on oath of such demand, and of refusal or neglect to comply therewith, to summon before him the person refusing or neglecting, and on being satisfied that such demand ought to be complied with, to order such information to be given and such production to be made within a reasonable time to be appointed by him ; and any such person who shall refuse or neglect to comply with such order shall for every such offence pay to such owner of copyright or other person aggrieved the sum of *five pounds*, and such refusal or neglect shall be *primâ facie* evidence that the person so refusing or neglecting had full knowledge that the article or thing imported, purchased, or obtained was an unlawful copy, repetition, imitation, or work of fine art.

A former clause gives power to search any premises suspected to contain piracies, and to seize them if found. Hence it will be seen that the Bill is constructed to prevent piracy as far as possible. In the new Bill the price for registration is to be one shilling, as heretofore; and for a certified and stamped copy of the entry two shillings and sixpence will be charged. This certified copy will be accepted as *primâ facie* evidence in legal proceedings that the registration has been duly effected.

Clauses 33 and 34 are quite new. The former provides that any inaccuracy in the registration at Stationers' Hall shall be no defence in case of prosecution, unless the Court be of opinion that the inaccuracies were of such a character as to cause a misapprehension on the part of the offender. The latter clause gives power to amend a registration. Upon written application the registrar of the Stationers' Company may make any correction in the name, style, place of abode, &c., of the owner of the copyright. The charge for making the amendment is fixed at one shilling for each entry corrected. This projected Bill, if it pass into law, is to take effect on the 1st of January next year.

We regret to find there is nothing in the Bill, if it pass the House, to make it retrospective with regard to such photographs as have from time to time been duly registered, under the impression that the registration was being effected in strict accordance with the requirements of the existing Act. We refer to such pictures as have been taken by paid assistants, as in the well-known Nottage-Jackson case, and were registered in the name of the employer. In all such work there is now, practically, no copyright whatever, notwithstanding that it was registered under the *bonâ fide* impression that all had been done that the law required, and this, up to the decision in the case referred to, was never before questioned.

No doubt this omission is, in great measure, due to photographers, as a body, being so generally apathetic with regard to their commercial interests in the matter of copyright. We have on several previous occasions directed attention to the necessity of professional photographers—particularly those who publish their works—banding themselves together to watch over their interest in any new Copyright Bill that might be introduced. It is scarcely possible that the gentlemen who are associated together in promoting the new Bill have any practical experience in what is actually required by photographers, but, doubtless, they will be open to any suggestions if brought forward in a definite form. So far as we are aware our advice has been disregarded. Possibly, had the desirability of making the Act retrospective, so as to meet such cases as those referred to, been brought prominently before the promoters of the present Bill, a clause might have been inserted which would have remedied the present unsatisfactory state of affairs.

Some of the clauses of the Bill, as at present framed, if it pass into law, will materially affect the system of business now being practised by many professional photographers. Next week we shall make some further remarks on the Bill as it now stands, and point out some of its most salient features affecting photographers generally, and professional portraitists more particularly.

THE PERMANENCY OF SILVER PRINTS.

The discussion on Mr. E. Dunmore's paper on *Old Photographs*, in which prominence was given to the question of the permanency of silver prints, again brought before thinking men a problem of paramount importance to the wellbeing of the art and its professors. It is one that is too apt to be lightly cast aside as a threadbare topic, the interest in which has quite ceased, and so-forth. The interest in the subject ought never to cease. Continued observations on the facts of fading, and a careful superintendence of the practice of those to whom printing operations are deputed, should be carried on by all who love their art and have a respect for their profession. The composition of a gold-toned print is complex and uncertain to an extent that forbids any conclusion of value to be drawn from their supposed composition, so that the results of actual practice, guided by certain known chemical facts regarding the production and toning of the picture, are all that have to be relied upon at the present day to enable us to solve the question—"Can a silver print be permanent?"

There is a tendency at present to propose a return to the older methods of toning; but we think a very complete discussion should take place before any such decision be arrived at. It is now about a quarter of a century since the method of toning which receives the name of "alkaline" was introduced. It was before the prevalence of the *carte* mania, and when that became so very pronounced photographers generally had had every opportunity of forming a judgment as to its possibilities, relatively and absolutely. Have any new facts been since discovered to overturn the unanimous verdict which the practice of photographers showed forth so clearly?

Those of us who are familiar with the photography of a score of years ago know very well the sort of thing the print from the old toning and fixing bath used to be—very beautiful on plain and very rich on albumenised paper, frequently permanent in the former and usually fading in the latter in a very short time—a fading quite different from the familiar alteration undergone by prints of the present day. If silver printing, as then practised by the leading men of the day, were universally carried on under the alkaline system, there must have been most excellent reasons for it.

Mr. Mayall may be said to have been at the head of professional photographers at the distant time we refer to—certainly as to the magnitude of his business; and we believe we are correct in instancing him as the last prominent photographer of the time to continue the gold toning and fixing system in the routine of the work of his establishment, his results having all the peculiar richness that so characterised that process. But in time he also abandoned it and took to alkaline toning. It would be interesting to know whether it was from a conviction of the non-permanent character of the old process, or from the greater facility for quick "output" offered by the newer.

Those were not times for a professional photographer to play at experimenting. He had to make his election; he had to decide upon the tools to use or his harvest time might pass. The election of the process to be employed came at a time when the immense increase of photographic operations was so great and so sudden that we may fairly believe considerations as to permanency were not the only ones actuating the general body of photographers. The time has now come when the question may be re-opened with the advantage of a vast accumulation of facts having been collected, and with large numbers of capable and earnest men being connected with the science.

The question is twofold in its aspect. Here we have two processes decidedly different in their mode of execution, and, to the best of our belief, embodying chemical changes of a very opposite character. Does either present possibilities of permanency, whether as at present carried on or under any possible alteration of conditions? It is the answer to this question that creates the uncertainty and confusion which undoubtedly exist, and which are increasing in intensity at the present time. It is unquestionable that many prints may now be seen toned by the old method of toning and fixing in one operation, which, though twenty or thirty years' old, are still very beautiful and apparently unfaded. There are also a large number of photographs still to be found which owe their tone to "alkaline toning," and which are equally beautiful, and also apparently as free from fading as the day upon which they were first produced.

We cannot, however, forget that the outcry against fading was very strong when the old method was in vogue, and perhaps the chief consideration that led to its abandonment was the promise of permanency given for alkaline-toned prints. Many books at one time were illustrated by the prints toned in the old way; but they faded so very rapidly that a reproach was very quickly cast upon the art from which it has never entirely recovered in popular estimation. Prints toned by the present method have also faded in large numbers; but it is our opinion, arrived at after a long and most careful weighing of evidence, that the proportion which of late years faded photographs have borne to unfaded is far less than that relatively borne by prints a quarter of a century ago.

It cannot be denied that the existence of even a few pictures after the lapse of a score of years indicate that fugitiveness of results cannot be inherent in the process, though it may be so complicated by side issues, so to speak, which cannot be thoroughly worked out, that want of permanence is the actual character of the results. That character attaches more to the old than modern processes.

Having thus laid the ground for a fair discussion of the process on its merits, we propose in our next to bring forward the more definite conclusions which it appears to us may be drawn. We may conclude by saying that we are justified in believing the chief distinction between the results of the produce of the two processes is that in the new any fading that supervenes is not necessarily in the print itself, but is owing to external influences; while in the old, not only is the print subject to the same external influences, but in the majority of instances it also contains within itself the germs of fugitiveness.

It is not often that photography gains the unqualified approval of the artist or art-critic; but so great an authority as John Ruskin has paid a very high compliment to a photograph. Referring to an ink-photo. portrait of himself, printed by Messrs. Sprague and Co., he writes:—"The portrait is out-and-out the best yet done of me."

It is a new feature in the character of an operator that is sought by an advertiser in another column. The operator, preferably a lady, must "have tact to cope with the ignorance and manners of a shabby-genteel neighbourhood." The neighbourhood, however, is one that is far from considering itself "shabby-genteel."

By the way, it is news to us that the unit of time, the second, belongs to the metric system, nor did we know that it was due to the originators of that mode of measurement; yet, in the article described in another portion of our columns, *La Nature* speaks of "the illustrious founders of the metric system, and the admirable system of weights and measures they have founded. All scientific measurable quantities are now expressed in terms of the three fundamental units—the centimètre, the gramme, and the second."

Willesden paper—a communication on which was recently read before the South London Photographic Society—was the subject of a paper read before the Society of Arts the other day, and which seemed to create considerable interest. It appears that the manufacture may be said to have been in hand for a considerable time, but many practical difficulties have stood in the way; they are, however, now removed, and a very large demand ought to spring up for the material. We see nothing whatever to stand in the way of its employment for many photographic purposes. For temporary studios it possesses manifest advantages, as also for the many little odds and ends in alterations which a photographer more than most men is so frequently carrying out. As a temporary roof, even, during summer months it must be of great value, while for dishes for development it should form a very valuable cheap substitute for the expensive ebonite. The Willesden Company make a solution for uniting the surfaces together, though experience in its use is required to perform the operation satisfactorily. The *rationale* of the manufacture is simple:—An ammoniacal solution of copper, which possesses the property of dissolving cellulose—paper, &c.—is allowed to partially act upon the surface of the material selected, which is then dried, when it has a varnish-like, impermeable surface of dissolved paper. Very full details of the process and its application at Willesden are to be found in the *Journal of the Society of Arts* for May 16th, to which we refer those of our readers who may desire further information.

When "solar enlargements" were more in demand than they now are, an instrument for keeping the rays of the sun in a constant direction would have been an important consideration; but its use at the present time would be more for astronomical or spectroscopic photography, for which, particularly if it were not expensive, there should be a demand. Dr. Johnstone Storey described such an instrument before the Royal Dublin Society, there giving to it the name "local heliostat," on account of its being capable of use anywhere in the British islands without any special adjustment being needed. He stated that this local heliostat had hitherto been made with mirrors about six inches by three for use in physical laboratories; but the design has been rendered so simple that it could be made at a small cost with a mirror as large as a toilet glass and driven by a cheap, common clock—a form which Dr. Storey points out would render it useful in photography.

Solar photography formed the chief topic of discussion at the last meeting of the Royal Astronomical Society, our esteemed contributor, the Rev. S. J. Perry, of Stoneyhurst, having started the discussion by an interesting paper on solar spots. Colonel Tennant rather objected to drawings of such appearances. "What we want," he said, "are photographs of sun spots on a larger scale than they have hitherto been taken, so that we may study the rapid changes which take place." This was being done on a large scale at Potsdam, it was stated, but not with sufficient frequency. Mr. Brett caused

H. BADEN PRITCHARD, F.C.S.

INK-PHOTO, SPRAGUE & Co LONDON.

some laughter by remarking that "it is easy to exaggerate the accuracy of photographs. Photographs are liable to misrepresent appearances unless they are taken by artists."

This is a very far-reaching assertion, as artists are usually supposed to fight shy of photography. They, or some of them, let others photograph, and "set" the results in the framework of an evolution of their inner consciousness.

Mr. Norman Lockyer reminded his hearers, at the same meeting, that the subject of good observational work was necessarily mixed up with the "brutal question of finance." He believed that all future observations would be made photographically. "No one now, for example," he said, "would think of drawing the nebula of Orion after what Mr. Common has done; and, if we are to do anything for the people who come after us, we must hasten to obtain a complete photographic catalogue of the whole heavens. We picture to ourselves, in a hundred or thousand years hence, a gallery filled with photographs which will give a complete picture of every part of the heavens, from the North Pole to the South. The great telescope will be charged with twelve plates at a time, which can be exposed by means of an electric magnet, and the whole work of the observer will consist in reducing and comparing the photographs. I hope members of the Society will agree with me that it is our duty to do what we can to provide such a celestial library to those who come after us."

We can cordially re-echo Mr. Lockyer's wishes, and we should be glad to find that, whenever such work is carried out, those for whom such photographs are taken may really see them as they are produced, and not through the translation of an engraving executed by an artist, possibly one who knows nothing of either photography or astronomy. We would again impress upon all who are connected with such work the desirability of letting photography tell its own tale. If it be the valuable aid to science which is generally admitted, why should its evidence be smoothed and made pretty to such an extent that deductions may be drawn from incorrect premises where rigorous exactitude should obtain? We shall not tire of harping upon this string till we see photographs of spectra, sunspots, stars, and comets—in fact, of all phenomena of scientific interest—brought before the scientific public as photographs (it should be known by every one now that permanency can be easily ensured) and not as pretty examples of the engraver's art.

With the unerring certainty of the camera to check too exuberant exercise of imagination the illustrated papers—at anyrate in scenes near home—may be expected to keep fairly close to literal truth, and photography in that sense subserves a most useful end. Thus, the recent earthquake in Essex offered a fine field for exaggeration; but negatives have been secured of the effects, and at the Royal Society's *conversazione* the week before last photographs of the damaged buildings were shown, that all might see the actual extent of what really was a disaster.

THE LATE H. BADEN PRITCHARD.

The late Mr. H. Baden Pritchard, whose sudden death was briefly announced a week ago, and whose portrait embellishes our present number, was the third son of the late Andrew Pritchard, well known as a microscopist and the author of the *History of Infusoria*, as well as the constructor of diamond microscopic objectives of high refracting power. Mr. H. Baden Pritchard was born in November, 1841, and at the age of twenty entered the Royal Arsenal at Woolwich, where he remained without intermission until the date of his death, and where, many years past, he had had the direction of the photographic department.

In 1868 Mr. Pritchard joined the Parent Society, to the council of which he was elected in 1870. Two years later he became its Honorary Secretary—an office which he continued to hold for three or four years—and in 1883 was elected one of the Vice-Presidents. On the formation of the Photographers' Benevolent Association Mr. Pritchard was elected Honorary Treasurer, which office he held continuously to the time of his death. Mr. Pritchard contributed numerous papers to the Parent Society, and occasional articles appeared from his pen in various journals, but chiefly in the *Photographic News* with which he was intimately connected as a contributor for many years, and of which he became managing proprietor on the death of Mr. George Wharton Simpson, a little more than four years ago. But photography alone did not claim Mr. Pritchard's energies for he was a prolific contributor to general literature, the range of his powers extending from newspapers leaders, scientific essays, and lighter magazine articles to three-volume novels. In the last-named department he gained some distinction with *Dangerfield*, *Old Charlton*, *George Vanbrugh's Mistake*, and *The Doctor's Daughter*, while his *Tramps in the Tyrol*, and his latest effort—but just published—*A Trip to the Great Sahara with the Camera*, by "A Cockney," showed his capabilities as a descriptive writer.

His connection with literature necessarily brought him in contact with men of all sorts and conditions within the circle which is supposed to constitute "Bohemia;" but the modern Bohemia differs widely from the shady and loose mode of life with which tradition and outside popular opinion are too ready to connect the name.

A member of the Savage, Whitefriars, Urban, and other literary clubs, Mr. Pritchard was intimate with many of the foremost men in connection with literature, art, science, and the drama, and his bright, genial disposition, his fund of humour, and his kindly nature made him friends everywhere. In social life he was especially a favourite, and whether the occasion were a children's party or a more sober literary gathering he was equally able and willing to contribute his quota to the general enjoyment. Many of our readers may have had the opportunity of hearing some of his humorous songs—a number of which were his own composition—at recent annual dinners of the South London Photographic Society and Photographic Club, while those who have the *entrée* of the narrower circles of the Whitefriars and Solar Clubs are aware that he was one of the moving spirits in both.

Mr. Pritchard was passionately fond of travel, and had penetrated almost every country of Europe, with many of which he was nearly as familiar as with England. His latest journey, from which he returned but a few weeks ago, was to Algeria and the Great Sahara, and already his experiences in that new field have been printed and published.

In 1873 Mr. Pritchard married Miss Evans, whom he met at the house of his friend Mr. H. P. Robinson. This lady and four children survive to mourn his untimely loss—a sorrow that will be participated in by a very large number of friends in the circles of photography, literature, and art.

The funeral took place on Thursday, the 16th instant, at Abney Park Cemetery, within but a short stone's-throw of the last resting-place of his former friend and predecessor, G. Wharton Simpson. The hearse bearing the coffin (heaped high with flowers and followed by several private carriages) arrived from Blackheath shortly after half-past four. A brief address took place, and the coffin was lowered into the grave where already lie his father, a sister, and a nephew; and, after a last look from sorrowing friends, who again showered flowers and wreaths upon the coffin, the crowd of mourners separated.

In addition to the immediate relations of the deceased a very large concourse, including many ladies, assembled in the cemetery. We counted upwards of thirty faces from amongst the photographic friends of the deceased, while, in addition, there were many members of the Savage, Whitefriars, and other clubs to which he belonged, including amongst them leading representatives of science, literature, art, music, and the drama.

Looking around on the sea of faces during the delivery of the mournful address, it was easy to see that no mere feeling of curiosity or of formal duty had drawn many to the spot. The sorrow was unmistakably genuine; and the large attendance, despite the fact that no public notice had been given of the sad event, spoke volumes for the esteem in which Mr. Pritchard was held.

Our portrait is from a photograph by Chevalier Lafosse, of Manchester, and is remarkably characteristic of our departed friend.

PACKING DRY PLATES.

This is just the time of the year when such questions as that of the best method of packing dry plates are likely to assume an importance in the minds of many landscape photographers which they do not possess during the stay-at-home period of the "off" season. In fact, as the photographer begins to form his plans for the coming campaign or for his summer holiday he will, if he be wise, pass in review his experience of the previous season, with the object, wherever possible, of improving his arrangements.

To the travelling photographer there is, perhaps, no single question which has given rise to so much doubt and difficulty as that of packing plates. I do not, of course, refer to mere packing for storage purposes, but packing for travelling, where it is necessary to combine under the head of general convenience the qualities of compactness, portability, facility for packing and unpacking, and, of course, safety from breakage. There are many ways of securing each of these qualities separately, but perhaps *the* perfect combination of the whole remains yet to be discovered.

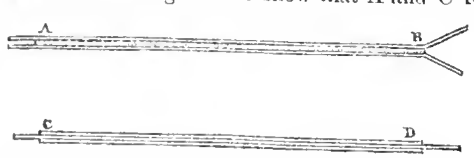
In the course of many years' dry-plate work I have tried, I think, every method of packing that has been suggested—from the bulky grooved plate-box to the mere insertion of slips of cardboard between the borders of the plates. The comparative hardness of the gelatine film, and its consequent less liability to injury than collodion, renders the matter of packing somewhat simpler nowadays; but, on the other hand, the greater sensitiveness necessitates a method which enables the plates to be unpacked, transferred to the slides and repacked with the utmost celerity, and, sometimes, in absolute darkness, in order to avoid fog. A plan that I used for some time with satisfaction on short journeys consisted in simply placing sheets of smooth tissue paper between, and in contact with, the surfaces of the films; but I found that if kept for a few weeks in this manner the plates became liable to markings of various sorts.

About this time I noticed Mr. England's method of using cardboard masks the size of the plate with the centre cut out, leaving a narrow frame an eighth or three-sixteenths of an inch wide, which, when placed between two films, came in contact only with the borders. Here seemed to be the very thing that was required; but, upon making inquiries of a mount-cutter for a supply of such masks made of very thin cardboard, I found he would only undertake the order at a price that was perfectly prohibitory, the separating masks costing about twice as much as the plates. I then set about building up a supply of the frames after the manner mentioned by Mr. England, by joining strips of card by means of squares of paper pasted on to the corners. The process was a slow and tedious one. The frames were not always square, and, when made, were very iable to break at the corners; but the three or four dozen I made answered their purpose so much better than anything I had previously used that I resolved to adhere to the principle, and, if possible, improve the method of manufacture.

I think I may say I have succeeded in simplifying the method and accelerating the speed of manufacture, and in producing a mask which is practically as strong as, or even stronger than, a cut-out cardboard one; and, as the method will be useful to others, I will briefly give it.

The weak point in Mr. England's masks is the difference in strength between the cardboard and the paper corners; if the mask be bent or strained the paper breaks. It struck me that by building up the masks of different thicknesses of paper instead of cardboard, and dovetailing, or rather "mortising and tenoning," the corners together the necessary strength would be gained; but at first sight the trouble of manufacture seemed likely to be greatly increased. After one or two experiments, however, I found in the latter respect the reverse to be the case. Here is the method of working:—

Take any good smooth and tolerably-stout paper, and cut it into pieces of any convenient length and of the following widths—the length is immaterial, the width important:—Two strips a quarter of an inch *wider* than one dimension of the plate, and one strip an eighth of an inch narrower than the same dimension; then two strips an eighth of an inch *narrower* than the other dimension, and one a quarter of an inch wider. The two sets of three are then pasted together sandwich fashion, with the two longer (or shorter) strips outside and the odd one in the centre, as shown in the diagram, which represents an end section of the compound sheets. An examination of the figure will show that A and C form what



the joiner calls a "tongue and groove." When quite dry, the two surfaces of the projecting portions at C and D and, if necessary, the inner surfaces at A and B are well gummed (the latter being opened, as at B, for the purpose), and again allowed to dry.

We have now a three-sheet cardboard with its edges tongued and grooved. By means of a sharp penknife and straight edge the sheets are cut into strips, three-sixteenths of an inch wide, in the direction of A B, C D. These strips, which present the same sections as in the diagram, are fitted together after the manner of a school slate-frame, the gummed extremities being moistened with the tongue, placed together, and pressed into contact with the thumb and fore-finger—four such operations, which occupy less than a minute, completing the frame.

As an example, suppose the masks are required for a half-plate ($6\frac{1}{2} \times 4\frac{3}{4}$): we cut two strips of paper $6\frac{3}{4}$ inches wide and one $6\frac{1}{8}$ inches for one dimension, and one strip 5 inches and two $4\frac{5}{8}$ inches wide for the other dimension. If the composite sheets are cut into strips three-sixteenths of an inch wide they will form, when fitted together, masks one-eighth of an inch smaller each way than the plate, the corners crossing like an Oxford frame. When dry the corners are trimmed square with the scissors. The masks made in this manner will bear any degree of rough usage within reason without breakage, and they form the best means of packing either plates or negatives that I have ever tried. In the course of a single evening a sufficient number may be made to pack a gross of plates. I have timed myself and find that, having the composite sheets ready to cut up, I can easily cut the strips and put together six dozen masks (sufficient for a gross of plates) within an hour and a-half; so that however complicated the description may look on paper there is but little trouble in practice.

With regard to the completion of the packing of the plates: I place them in pairs face to face with a mask between, and these are wrapped in half-dozens, two such packets (sometimes three if the plates are thin) being enclosed in one of the cardboard boxes in which commercial plates are issued. For convenience in unpacking and repacking when away from home only one thickness of orange paper is placed round each packet inside the box; and for protection from light I trust to the box itself and its outer wrapper of brown paper. If commercial plate-makers would expend more of their energies in wrapping the boxes and less in wrapping the plates they would, I think, save a good deal of dark-room bad language.

For convenience of packing in absolute darkness, or by the feel as in a changing-bag, I put the plates direct into the box without wrapping. The first plate is laid face upwards and on it a mask, these being pushed into one angle of the box, the two containing sides of which act as guides; the second plate follows face downwards, and so on until the box is full. The ordinary commercial boxes will be found to allow sufficient room for the insertion of the finger to pick out the plates; and this extra space, when the plates are packed, can be filled up with a wedge of paper to keep the plates firm.

In conclusion: I can recommend this method of packing to all who study comfort in travelling. I also apply it myself to the storage of negatives, which, if kept in the usual grooved boxes, take up sadly too much room. I keep mine in the ordinary boxes in which the plates are sent out, with a memorandum of the numbers of the negatives pencilled outside for reference. C. Beckett Lloyd.

THE NEW STANDARD OF LIGHT.

Writing of the International Conference upon standards, whose conclusions upon the light standard we described in our last issue, *La Nature* speaks of the great stress it lays upon the subject. "Up to the present time," it says, "the quantity of light emitted from a given source was estimated by means of arbitrary units. In France it was the Carcel lamp, and in England and Germany the candle. Other standards have been proposed—the Schwendler, Girond, Vernon Harcourt, Siemens, &c., standards. None of these lights satisfied the conditions that ought to be fulfilled by a representative standard. These conditions are indeed numerous. The standard must be constant, it must be able to be reproduced at any time and any place, it must be of a convenient size relative to the quantities to be measured, and, in fact, it must lend itself to an exact comparison with those quantities. The last condition involves a requirement particularly difficult to satisfy—that of colour. The standard itself ought to possess a sufficiently-white colour to be comparable with modern lights, and in all cases to show in the spectroscope the whole range of the scale of colours, so that light of any colour whatever may be compared with that of the standard in each part of the spectrum."

This, as our readers will see, has a most important bearing on the use of such a standard for photographic purposes; but it necessarily adds to the difficulties of finding an efficient substitute for the fused platinum. "This comparison," the editor continues, "is necessary in exact measurements. All natural lights being formed from the superposition of different simple lights, the intensity of each of these simple lights should be measured by comparison with the corresponding portion of the spectrum."

M. Violle had proposed to the International Congress, in 1881, a scale satisfying all the required conditions. It is the light emitted by a square centimètre of fused platinum at the temperature of solidification. This temperature is very great (1775° C., according to M. Violle's measurement), and, in consequence, the light emitted is whiter than that of the Carcel lamp or a candle; it most nearly approaches that of an incandescent electric light. The radiation, like the temperature, is absolutely constant during the whole period of solidification, and it can always be repeated exactly similarly, since it is derived from a natural phenomenon unvarying of itself. The light is the same from all points of the radiating surface—a very valuable quality which enables any desired multiple of the unit to be obtained in a moment by taking a surface two, three, &c., times as large.

Some practical difficulties concerning the production and maintenance of this unit were the only obstacles in the way of the conference of 1880 immediately adopting it. These difficulties have been cleverly surmounted by M. Violle in a series of experiments carried on for the last eighteen months in the cellars of the *Ecole Normale;* and the conference of 1884 has definitively adopted his unit.

SOME EXPERIENCES OF A BEGINNER.

[A communication to the Leeds Photographic Society.]

The use in the dark room of light which has passed through ruby glass is attended with many disadvantages, and a yellow light is far preferable. The light from a small benzoline lamp, after passing through one thickness of "canary medium," exerts a considerable effect on a gelatino-bromide plate if the latter be exposed directly to it; but this light can be used with safety if care be taken to keep the plate covered up during development, and to expose it to the light no more than is necessary for proper examination.

Development.—Any method of development in which the whole of the ammonia is added to the pyro. at once gives the operator very little control over an over-exposed plate, and indeed throws away the principal advantages of pyro. development. The ammonia solution should be moderately strong and ought to be added gradually to the pyro. as the course of development indicates. The relative proportions of ammonia and ammonium bromide differ greatly in different formulæ. In some the amount of bromide is much too small; in a few it is too large. A solution containing—

Ammonia, ·880	1 ounce,
Ammonium bromide	½ ,,
Water	9 ounces,

forms a convenient stock solution for all makes of plates. One drachm of this solution added to one ounce of water containing two grains of pyro. will develope a properly-exposed quarter-plate.

When sodium sulphite is used with the pyrogallol in the developer the solution becomes much less highly coloured, and remains clear during development; hence the progress of the change can be more easily seen than with the ordinary developer. The shadows are kept clearer, and there is much less tendency to fog. But the sulphite exerts a certain restraining action, and in order to gain good printing density the plate must be left in the developer much longer than is necessary when using plain pyrogallol. The amount of sulphite usually recommended is unnecessarily large; twice as much sulphite as pyrogallol is quite sufficient, and the solution should be acidified with sulphurous acid in preference to citric acid. My experience refers only to solutions which have been kept not more than a week, and does not extend to solutions which have been kept for a long time.

Intensification.—When intensifying by means of mercury the gradations of light and shade in the negative can be preserved if care be taken not to keep the plate in the mercury solution too long, and if in the subsequent treatment the ammonia be added gradually instead of all at once. Dr. Eder's uranium method usually gives satisfactory results, and has the advantage that uranium ferrocyanide is soluble in alkalies; hence, if the intensification have not been satisfactory, the deposit can be removed by treatment with dilute ammonia, and other methods of intensification can afterwards be applied.

Reducing Negatives.—In reducing negatives by means of ferric chloride it is best to use a moderately-dilute solution, and care must be taken not to keep the plate in the liquid too long. A convenient strength of solution is—

Ferric chloride	1 drachm,
Water	8 ounces,

and the plate should be allowed to remain in it for one, two, or three minutes, or longer, according to the amount of reduction required. The brown stain, which is usually produced, can be removed by means of alum and citric acid. This method of reduction diminishes the contrasts in the negative.

In all cases where processes are applied to plates which have been dried, and especially if they have been alumed, it is advisable to leave them to soak in water at least three hours, in order to bring the films into a homogeneous condition.

Reproduction of Negatives.—Negatives can be readily reproduced by making a transparency by the ordinary contact method, and then printing a new negative in the same way from this transparency. The new negative may be even better than the original, since contrasts can be increased or diminished at will by varying the proportions of pyrogallol, ammonia, and ammonium bromide in the developer.

Instantaneous Work.—Instantaneous photographs taken with very short exposures are valuable from a scientific point of view, but are frequently inartistic. Any impression received by the retina of the eye persists for about one-tenth of a second, and it follows that all motions taken place during this interval are compounded by the eye into one resultant motion. If the exposure be only one-fiftieth of a second, or even less, phases of motion are represented which are never actually seen as distinct positions; and to obtain artistic pictures the exposure should not be less than one-twelfth to one-fifteenth of a second. Very good pictures of such subjects as breaking waves can be taken with an exposure of this duration made with a simple drop shutter.

C. H. Bothamley, F.C.S.

ON THE CORRECT REPRESENTATION OF COLOURS BY PHOTOGRAPHY.

The task of all reproducing arts, to which photography belongs, is to represent the tones of the original in their proper proportionate values—that is to say, the light shall be represented by light and the dark parts by dark. That a photograph does not rightly fulfil this task, when dealing with a coloured original, is well known; it, indeed, often gives the opposite of the original. The light part, if it be yellow, often comes out dark, and the dark part, if it be blue or violet, white. This contrariety is most vexatiously distracting when paintings have to be copied, but that it also displaces values in portrait photography every photographer knows.

Until now negative retouching has been employed successfully to grapple with this drawback. Since Milster showed, eighteen years ago, what a distinguished artist could make of a negative after an oil painting, the reproduction of oil paintings has grown to be quite an important branch of German art industry, which has considerably injured the copperplate and lithographic branches, and has in the shortest time made the most striking masterpieces of modern time accessible to the whole world. But the progressive spirit of discovery is not contented with the present, however good it may be. The reproducing photographer sets himself new and great tasks—the replacement of the silver print by a mechanical process, and the substitution for retouched negatives of direct photographs upon plates specially prepared to offer sensitiveness to colour.

The first of these tasks has already frequently occupied our attention in these pages, and efforts to produce something resembling Goupil's photo-engravings have, as is now well known, been crowned with success. The second point, however, still merits a more particular description of the newest efforts which, in the matter of representing difficult colours, especially in old pictures, give astonishing results. We saw lately, at a meeting of the Association, two reproductions of an old Italian painting—one by Braun, of Dornach, and the other from a Berlin establishment. The difference was as between light and day. The Berlin one showed broad black spots, where Braun's one was full of details which a person could see were not owing to retouching on the negative. Equally astonishing was the difference between Braun's copy and that of a Münich firm of a Cornelius fresco, and, further, a copy of a choir stall with coloured interstices in the Berlin Museum, in which the values of the tones were most faithfully maintained. Here the problem of representing in almost their true proportionate value at least some colours was solved, and by the practical application of the principle, discovered by me eleven years ago, that bromide of silver can be rendered sensitive to the so-called chemically-inactive rays by the addition of substances which optically absorb these rays (*Mittheilungen*, vol. x., p. 233).

This discovery was at the time of its publication doubted by men such as Carey Lea and the late Monckhoven, and its alleged incorrectness was attempted to be shown by experiment. The British Journal of Photography also laughed at the whole thing, and it was not until a year after that Becquerel proved experimentally that these observations were correct. Still, men like Captain Abney continued to doubt as before. In 1875, on the occasion of the British expedition to observe the eclipse of the sun, Major Waterhouse, at Calcutta, saw my photographs of the red and yellow parts of the spectrum, taken on coloured collodion. A year later he repeated this experiment with the most complete success, and indeed added new dyes to the regions of his researches. Until that time the thing had only been worked out scientifically. But so far back as in 1873 I had the good luck to photograph a dark blue band upon an orange ground in the correct proportionate shades—that is to say, the blue dark and the yellow light.* Yet years passed away before any practical use was made of these observations. In 1877 Ducos du Hauron and Albert made a beginning. They aimed

* For corroboration of all these statements see *Mittheilungen*, vol. xi., p. 97; vol. xii., pp. 196 and 247; vol. xiii., pp. 16, 197, 223; vol. x., p. 257.

high. They not only wished to represent colours by monochrome, but colour by colour—an attempt which offered great difficulties, because in the latter case nature does not itself counterfeit its own colours, but these have to be selected by the printer. (See Vogel's *Lehrbuch*, 3rd edition, and *Mittheilungen*, vol. xiv., p. 176). Albert and Ducos used coloured collodions and coloured glasses. With the latter they cut off the access to the plate of colours, the action of which they did not wish. (I had already employed this means in *Mittheilungen*, vol. x., p. 237.) The labours of Cros, of Paris, were parallel with these experiments.

Lately, attempts have been made to apply the same principle to gelatine plates also. I published my experiments in that direction in *Mittheilungen*, vol. xvii., p. 15. The best medium of absorption for these plates proved to be eosine, which has also been used for collodion plates by most investigators who have experimented on this point. The eosine-gelatine plates of Clayton and Tailfer are already a commercial article. The action of eosine upon bromide of silver is explained in my *Lehrbuch*, and made clearer by an illustration. By it the sensitiveness to yellow is considerably increased, and that to blue lessened. The latter effect is also apparent when other dyes are used. This circumstance—the weakening of the sensitiveness to blue along with the increase of the sensitiveness to yellow—is of very great importance, since, were it absent, in photographing dyes the blue would act as powerfully as the yellow, and appear as light as the latter.

When I examined spectroscopically some of Clayton and Tailfer's plates I found that they were about twice as sensitive to yellow as to blue; their sensitiveness to red is, on the other hand, no greater than that of ordinary plates. The above-mentioned sensitiveness to yellow was, however, not sufficient to make it possible to take yellow pigments alongside of blue ones, and to represent their relative tone values correctly; for yellow pigments are very considerably darker than the yellow rays of the spectrum (Vogel's *Lehrbuch*, p. 157). I then tried whether it would not be possible to still further increase the sensitiveness of the plates to yellow, and, at the same time, to amend the faulty sensitiveness to red. *I have succeeded in doing both. I have prepared wet collodion plates which are at least eight times as sensitive to yellow as to blue, and, besides, exhibit a sufficient sensitiveness to red.*

The results are briefly:—1. Upon gelatine plates not only does eosine act, but also cyanine and methyl violet. Of fuchsine I have already said that it does so. These dyes, in accordance with the theory I propounded eleven years ago, render gelatine plates more sensitive to those parts of the sun's spectrum at which they show bands of absorption. But the sensitising action of dyes upon gelatine plates is very much less than upon collodion plates. The difference in that respect between bromide of silver sensitive to blue and that sensitive to indigo is the most striking (*Mittheilungen* for 1883, page 99).—2. The impression of light which many dyes suffer can be rendered developable. If, for example, fuchsine be exposed for a *very long time* to the action of the sun's spectrum, in the presence of nitrate of silver, the latter is reduced, and when treated with a physical developer (solution of ferrous sulphate) shows a distinct image. Since as yet there are but few substances which, like chloride, bromide, and iodide of silver, admit of physical development in presence of nitrate of silver, it would be interesting to see the range of such enlarged by organic substances. If one should succeed in rendering particularly sensitive to light organic substances available in this way, the basis of a new photographic process would be obtained. That fuchsine and other dyes exposed with nitrate of silver to the spectrum are only sensitive as above to the rays *absorbed* I merely mention as a matter of course. The correspondence which here shows itself between absorption and chemical action is wonderful, and offers the investigator a sure guide in further experiments. He who knows the absorption and how to judge of the spectrum can measure the action of the dye in advance.—3. Only dyes of high absorbing power act as sensitisers on the silver salts. The conditions under which a dye stuff acts as a sensitiser are different for each substance, and must be determined for each substance separately by experiments with the spectrum. Apparently it will prove on further experiment that many dyes which have until now been considered nactive are capable of acting. H. W. Vogel, *Prof.*
—*Mittheilungen.*

THE TEMPERATURES INSIDE GLASS STUDIOS.

Has the question ever been raised in the photographic world of the advantages and disadvantages of building glass photographic rooms with two surfaces of glass, the one twelve or eighteen inches within the other? Out here in Switzerland nineteen houses out of twenty, even the poorest habitations, have double windows, in moderate time the extra expense of construction being saved in the cost of fuel, less fire being then necessary to sustain the temperature of the room, in addition to the great extra comfort conferred and the freedom from draughts. The plan would somewhat lessen the light for photographic purposes, by giving four reflecting surfaces instead of two, and by giving two slightly absorbing layers instead of one; but in these days of quick gelatine plates these two objections may not be of practical optical importance. If, however, they were of importance, portions of the inner layer of glass might be made to slide away temporarily, during the time only of the taking of a portrait.

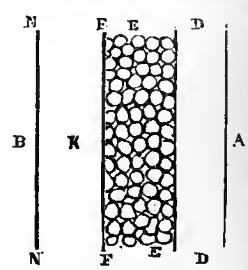
The extra cost of fuel with but one layer of glass is astonishing to those who have never tried the difference. If a glass door in a public Swiss café is not made double like the windows, but opens directly to the outer air, the seats near it are deserted by the frequenters, the temperature there being so much lower than in other parts of the room, for which reason a kind of double entrance is commonly constructed. In hotel bedrooms when the inner window is opened in cold weather a sudden chill is felt, because of the layer of cold air between that and the outer one. The distance between the two is usually about one foot, and in some few houses the intervening space is utilised as a small greenhouse, the lower part being filled with mosses, ferns, and flowers. One reason of this superior building here is that the Swiss house-dwellers are their own landlords, and land is a free article of commerce. Hence the houses cover more space, and the people have no interest in possessing "jerry" buildings—to tumble down as near the end of a lease as possible; they build solidly, and the bulk of the population have homes far more comfortable than are generally known in England. In England the people are overcrowded and squeezed into a very limited space in towns, so that it is not so easy to get extra room for the larger glass studios herein suggested.

Another item in the saving of cost of fuel in Switzerland is the stoves, in which all kinds of fuel can be burnt—but coke most economically. There is no smell from the stoves, this being avoided by giving them a much larger heating surface than is usual with us; the heat being spread over a larger area in the stove, the surface of the latter has a lower temperature than our small ones.

A Swiss room with double windows—the size of that in which the Photographic Society of Great Britain holds its meetings in Pall Mall—can be kept comfortably warm with coke by a Swiss stove at a cost of from one penny to twopence a day, although fuel is dearer here than in England.

The larger stoves are usually cylindrical, some of the old-fashioned ones for burning wood being as large as locomotive boilers placed on end, but the size of the modern ones is not so excessively large. Their chimneys consist of concentric thin iron rings, and are bent about near the ceiling in elegant curves, like the scaly tail of a dragon, so that by their great length they may give up all their heat to the room before they enter the stone chimney proper of the house. Here again, in the power of using large stoves, the Swiss feel the advantage of their great space inside towns and houses. There is a very thick lining of fire-brick between the iron exterior of the stove and the fire; in fact, after the large stove has been well heated it will warm the room long after the fire has gone out. The stoves have intelligently-made air and smoke valves, by which the combustion of the fuel is regulated more than by poking. The poker, in fact, is scarcely ever used, but is available if wanted. These stoves have also an arrangement for warming air inside as well as outside themselves, and of discharging the air so warmed into the room.

The accompanying diagram represents the side of one of a Swiss cylindrical stove, as manufactured by Herr Weltert, of Sursee, in which town he has the largest manufactory of the kind in Switzerland. In this cut A is the interior, or place of the burning fuel of the stove, and B the exterior. The inner wall, D D, is of fire brick, about three inches thick. Then comes a layer of small, rounded river stones, E E; these stones are a peculiar local variety, which will bear much heat without crumbling to pieces under it. F F is the inner iron skin of the stove, and N N the outer iron skin; between them is the air space K, in which fresh air from outside the house is warmed before entering the room. In the morning the stove is half filled with coke, on the top of which a small coal fire is lit to ignite the upper part of the coke below. The doors of the stove are then closed, and throughout the day the amount of combustion is governed by regulating the quantity of air supplied to the fire. The coke being lighted at the top, the fire consumes its own smoke and burns slowly. Several minor scientific details might be added, but what has been stated will give a general idea of the construction.

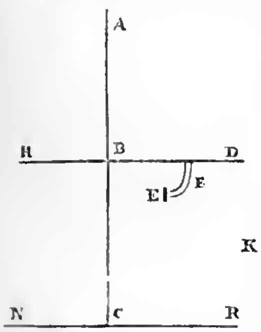


Another advantage of more household space, if it were as obtainable in England as on the continent, would be that those studios would be more numerous in which it is possible to use lenses of long focus. There is no doubt that lenses of short focus will not do, generally speaking, such good work as the others, especially in these days of quick plates. The best photographer in Milan scarcely ever uses his portrait lenses, although they are made by the best opticians of England and Germany; he finds that he obtains better pictures with an aplanatic doublet, partly because it has fewer reflecting surfaces. If ever I had to do with portraiture I should really try quick plates with a long-focus single landscape lens made to cover a plate much larger than that in use, employing at the same time a large stop. It would be a good thing if the brilliancy given by a single lens with only two reflecting surfaces could be utilised in glass-house portraiture. Besides the focus of a lens should always be as long as the distance at which the portrait will be held from the eye by any person viewing it, to give the best results.

All this implies the power of building a long and large glass house. One objection in England is the dirty air of cities caused by the fuel wasted in the form of coal-smoke; also the deterrent photographic influence of fogs when they enter long rooms. Interruptions of work from such causes would be infrequent, and it is possible to apply a remedy. The public could enter by one pair of double swing doors at the bottom of the stairs, and another pair at the top, so that they would only momentarily let in a little of the outside air on entering; whereas the bulk of the air in actual use in the room could be drawn through another channel, and be filtered from the dirt it had been carrying outside. Cotton wool is the best and cheapest material for filtering air. The air might enter the room through a pipe two feet long and one or two feet in diameter, loosely stuffed with cotton wool, and then be passed through the air-warming part of the stove before it escapes into the room. This plan would baffle the fog and dirt demons. The late Mr. C. F. Varley, the electrician, used to filter the air breathed in his earlier private residence, Fleetwood House, Beckenham, Kent. The house was subsequently purchased from him by Captain Halpin, of the Great Eastern steamship; I do not know if the apparatus be still there, but cotton-wool was the filtering medium employed.

As at present constructed nothing can be worse for temperature than a glass photographic room. It gives the heat of a greenhouse in summer, and is kept warm in winter by great expenditure of fuel, but with a layer of more or less chilled air near the glass. If constructed with double layers of glass it would be one of the best rooms in the world for temperature, air being such a bad conductor of heat. It is not the fabric of our clothing, for instance, which keeps us warm, but the air entangled in the interstices of the fabrics. Blankets are, therefore, so very warm because of the large quantity of air they entangle; and fur dresses, with the fur inside instead of outside, are about the warmest to be had by travellers in polar regions.

A double-surfaced glass house offers facilities for being kept cool in summer by cooling the air as it enters through the artificial channel. The English Houses of Parliament are the best-ventilated buildings in Europe, and the air for them is chiefly cooled in summer by means of the lowering of temperature produced by the evaporation of water. The principle may be explained by the aid of annexed diagram, in which A B C is the wall of the house; D B C R cloisters opening into a courtyard at K, and H B C N is a room for temperature-regulation beneath the floor of the house. A B H is the house, and the hot or cold air enters it from below through its perforated iron floor, on which is a string carpet of wide mesh. The foul air escapes at the top of the house, and is discharged through a shaft in the Victoria Tower, the draught being caused by a fire constantly burning at the bottom of the tower, on the colliery-ventilation principle. E is one of a series of metal buttons in the cloisters, against each of which a jet of water is driven through the pipe F. This water is driven with great force, so that it bursts into spray by impact on the button, which spray evaporates to some extent in the damp cloisters.



At B C are large sheets of very coarse canvas, through which the cooled air passes, and on which it deposits some of its London dirt, so that the canvas requires frequent washing. It is long since I examined these arrangements, but I have no doubt they are still in use, as the building is constructed to harmonise with them. Sometimes, in hot weather, unscientific members of Parliament open windows to cool themselves, forgetting that they are already supplied with cooler air than obtainable directly from outside.

To get artificially-cooled air into a glass room in summer it would be necessary, in the absence of a fire, to set up artificial circulation. This could be done by a long iron pipe, three inches in diameter, rising from the roof, with a gas-jet burning at its lower orifice inside the house. This plan of ventilation is common in Switzerland for public smoking rooms.

W. H. Harrison.

Werthenstein, Switzerland, May 1, 1884.

ON THE DETERMINATION OF THE DURATION OF THE EXPOSURE.*

II. Regular Circular Motion.—In order to produce a regular circular motion which can be photographed various means are employed :—

(*a*) *The Movement of the Index Hand of a Clock*, the pendulum of which has been removed. As one will immediately perceive, such an arrangement can only be used when the index is moved rapidly enough; but that would never be the case with an ordinary clock for really short exposures, because, even if the progress of such a one becomes sixty times faster owing to the removal of the pendulum, still the minute hand would only go round the dial once in sixty seconds, and one would not be able to demonstrate fractions of a second thereby. But if a second hand were there which would now pass round the dial in one second, if it stood out white upon a black ground it would be sufficient to demonstrate an exposure lasting from about one-sixtieth to one-hundred-and-twentieth of a second. For shorter exposures even that would still not be sufficient.

(*b*) *The Revolution of a Spindle Set in Motion by a Weight*, where a wind-sail serves as regulator.—Perhaps for the purpose now in view such a spindle running easily on a pivot, and furnished at one end with an indicator and also with a wind-sail, is the best instrument, because by the heaviness of the weights and the size of the wind-sail one has complete control over the duration of the revolution, and can accelerate it at pleasure. Of course the index must be white here also, and must pass before some kind of black dial upon which the divisions of a circle are marked off, from which the duration of the exposure can be distinctly read. The length of the exposure can also be easily ascertained even without such a division, since, if the indicator be as long as r, if it go round the dial n times in a second, and if during the exposure its tip have described the course d, then the duration of the exposure t is equal to—

$$t = \frac{d}{2 r \pi n}$$

c. The Course Passed Over During the Exposure by a White Rod Swung Round Regularly by a Man in Front of a Dark Background, or a White Ball Fixed to a String and Whirled Round in the Same Way.—Also by this method it is necessary, when determining very short durations of time, to swing the object round as rapidly as possible; each revolution should, indeed, not last longer than a second. The calculation is then made by means of the formula already given.

d. With the Help of Attwood's Falling Machine.—A powerful top weight is placed upon it, and when it has gone a considerable way one causes it to be raised by the ring, and photographs during the regular motion now produced.

e. The Movement of a Ball Running Downwards in a Groove of Known Inclination, and then proceeding in a horizontal direction.—This method is much less exact than the preceding. If x be the angle of inclination of the groove, then the accelerating force is $g \sin x$.

As Heavy as Possible a White Ball is Allowed to Fall from an Exactly-Known Height in Front of a Dark Background, and an Exposure is Made During the Fall.—The instantaneous shutter must be set free very quickly after the ball is allowed to fall. Now, if from the picture one ascertains that on the shutter being opened the ball had already got as far as s, and when it was closed as far S, then one knows that for the corresponding times t and T give the equations :—

$$t = \sqrt{\frac{2s}{g}}; \; T = \sqrt{\frac{2S}{g}}$$

From which, as the time of the exposure, we obtain—

$$T - t = (\sqrt{S} - \sqrt{s}) \sqrt{\frac{2}{g}}$$

This method is, perhaps, the most suitable for determining the length of very short exposures, especially if a great height be available for the fall. A very excellent ball is secured by filling a glass globe, silvered on the inside, with small shot, and letting it fall in front of a dark surface upon which the sun shines. The globe will then reflect an image of the sun of small diameter.

B.—The Objective or the Sensitive Plate Moves, or Both Move Simultaneously.

It is evident that by this method the time of the exposure can be determined if one take a bright, white rod or a similar circular spot in front of a dark background. Yet the two first methods of proceeding are hardly to be recommended, as it would be extremely difficult to endow either the plate or the objective with a regular, exactly-known, and well-isolated movement. It is otherwise with the third case. A camera can very easily be placed upon a pivot and made to revolve with a constant rapidity round a perpendicular axis. For this purpose a special camera stand will have to be constructed, the top of which can be made to revolve by means of a hand-winch. For less exact determinations it is also possible to take hold of the camera by one's hand and so turn it round; or, finally, one can suspend it to a cord revolving by being twisted, or to one of the revolving show-frame contrivances. Now, if the focus of the objective be f, the number of revolutions in the second n, and the distance traversed in the picture d for the time of the exposure t, one gets—

$$t = \frac{d}{2 f \pi n}$$

This method is, as one sees, very convenient, because it is not necessary, as in A b, first to settle the actual movement from the picture, because that is given almost directly by the measuring off of the picture by the aid of a short division. But, on the other hand, since it is difficult to make the revolution so regular and certain by this method as by that, it cannot, therefore, compete with it in respect to

* Concluded from page 512, vol. xxx., 1883.

exactitude; yet the ease with which a single person can, without other apparatus than a light camera, determine the duration of the exposure, makes this method seem especially worth recommending for most practical purposes. FRANZ STOLZE, Ph.D.

FOREIGN NOTES AND NEWS.

AWARD TO PROFESSOR VOGEL.—A NORWEGIAN PHOTOGRAPHIC SOCIETY. —THE BEHAVIOUR OF IODIDE OF CADMIUM TO ETHER.

AT an extraordinary general meeting of the Berlin Association for the Cultivation of Photography, held on the 16th ultimo, it was resolved to found a prize of 1,000 marks (say £50), and to award it to Professor H. W. Vogel as an acknowledgment of his discovery of the collodion process as sensitive to colour and in recognition of his services to photography in general and to this Society in particular, both as founder of the Society and as its guide and President. The process of which mention is made above is not a method of photographing in colours, but of representing colours photographically in their true values. A detailed description of the process, which Dr. Vogel has not patented, appears elsewhere. [See page 327.] It seems that for photographing paintings or other coloured objects the collodion process is far superior to the gelatine, but that the collodion plates had better be dry than wet.

In Norway a photographic society has been founded under the name of the *Del Fotographiske Selskab.* The office-bearers are—*President*, L. Szacinski; *Vice-President*, Fr. Klein; *Treasurer*, C. Wichman; *Secretary*, H. Abel.

In the *Chemiker Zeitung* Herr Georg Buchner calls attention to the very peculiar behaviour of iodide of cadmium towards the so-called "pure ether" of commerce, as it furnishes an easy and rapid means of testing the purity of the ether, and has also special merits in the case of ether which is intended for the preparation of iodised collodion for photographic purposes, as iodide of cadmium is also employed for that purpose. Herr Buchner observed the reaction in question once when he was preparing an etherial solution of iodide of cadmium. In a quarter of an hour the solution became yellowish, and by the end of a day it had become a brownish-yellow, while, at the same time, the solution first became turbid and then deposited a small quantity of a white precipitate. As the ether used did not discolour litmus-paper, and therefore seemed free from acid, and, as there did not appear to be any other impurities present, he at first thought the cause of the phenomenon must be that an etherial solution easily absorbed oxygen, and that that would give rise to the reaction observed by simultaneous separation of the iodine and formation in the ether of insoluble iodide of cadmium oxide. But, as every ether did not give the same amount of reaction, and as one sample of ether afterwards procured hardly gave any reaction at all, he became convinced that the cause must lie in some impurity in the ether itself. He then observed that the strongest reaction of all was given by a sample which had been supplied to him as the very *purest* absolute ether, and by another sample which he had himself rectified over chloride of calcium. A small quantity of ether distilled over iodide of cadmium furnished a distillate which remained perfectly indifferent to iodide of cadmium, even when heated on the water-bath, which otherwise accelerated the reaction. 22·0 grammes of absolute ether were distilled over iodide of cadmium. The distillate was colourless, and the almost dry residue was a brownish-yellow. The residue was flowed over with alcohol, when it dissolved, assuming a brownish-yellow colour, and throwing down a white precipitate. The precipitate was washed with alcohol and dried. It weighed 0·103 of a gramme. The brownish-yellow solution, containing the iodine thrown off, combined with the washing water, gave, when subjected to volumetric analysis, with one-tenth of normal sodium thiosulphate, 0·06096 of a gramme of iodine. This quantity corresponded to 0·17 of a gramme of decomposed cadmium iodide, from which one would find by calculation that there had been 0·118 of a gramme of iodide of cadmium oxide (of which, as shown above, 0·103 of a gramme was actually found). Though Herr Buchner is, for the moment, unable to give more exact details regarding the substances on which this reaction is produced in commercial ether, yet from the foregoing it is seen that the quantity is not inconsiderable, and that by rectification over iodide of cadmium the iodide can be purified from it. He thinks it is apparent that this impurity is the reason why iodised collodion often becomes so rapidly red. To test ether take about 0·2 of a gramme of iodide of cadmium in a test-tube, then add ten c.c. of ether, and place it for an instant in the water-bath. Should the ether be impure it will become coloured in a few minutes, the depth of the colour varying from pale to golden yellow. It will then become a brownish-yellow and turbid, and throw off a white precipitate of iodide of cadmium oxide. Under the same circumstances pure ether remains perfectly colourless.

EASTER MONDAY WITH THE CAMERA.

PORTSMOUTH is never at any time a dull place. The coming and going of men-of-war and of transports, the large garrison, the crowds of "blue jackets," and the annual fashionable influx into Southsea—all prevent its ever becoming so. When the town is *en fête*, however, and puts up her triumphal arches, decks herself with gay ribbons, and assumes her other coquettish airs, she is as lively as any Spanish city in carnival time. Those who had the good fortune to see her last Easter will not readily forget her attractions.

From Saturday to Monday the main streets of the borough were a gay spectacle. Above, every variety of flag and banner were festooned across from house to house, or fluttered from window or roof. Mottoes, devices, and illuminations glittered and glanced on every side. The pavements were crowded with uniforms. Blue marines and red marines, linesmen and dragoons, royal artillery and blue jackets, volunteer artillery and engineers, spruce London Scottish and grey Artists, riflemen, black, blue, red, and grey from the metropolitan corps—all swarmed and jostled and pushed from one end of Commercial-road to the other. Very serviceable the citizen soldiers looked, with bayonet and water bottle, blanket and haversack—ready apparently to go anywhere and do anything, more particularly to drink. Considering that on Saturday night there were some fifteen thousand men in the town order was wonderfully well preserved. There was only one disturbance of any consequence which I observed, where some regular engineers having given offence to a few volunteers a free fight ensued, in which a couple of sailors joined, fighting apparently like Hal of the Wynd—each for his own hand and with the strictest impartiality. In this skirmish the volunteers had decidedly the best of it, and remained in possession of the field.

Easter Monday morning broke bleak and raw, and it became a problem of some difficulty to know how camera and stand and carriers were to be conveyed to the top of the Portsdown ridge, some three and a-half miles from the town. Vehicles were at famine prices, and even the 'bus companies had run up their fares in a way which prompted all public-spirited citizens to "boycott" them. As my two companions and myself included ourselves in the category we proceeded to put our principles into practice—a resolution which led to sore heels, blisters, and much dust and exasperation. As far as we can learn, our abstention had not any perceptible effect upon the market value of 'bus shares. We have given up "boycotting" large companies since then.

Trudging along three miles of very dusty road with a camera in one's hand is not the most blissful of human employments, more particularly when the crowd upon the footpaths the whole way is so thick that you have to regulate your pace by that of others. You tread on the heels of those in front of you, and, while they are expressing their opinion of you and of your proceedings in flowery and scriptural language, you are yourself trodden on by those behind. Vehicles of every sort and description clattered along the causeway, and as no rule of the road appeared to be observed it was dangerous to go off the footpath for a moment.

The lines of Hilsea having been passed, the first sign of warlike operations became visible in the shape of a pontoon bridge thrown across the canal by the engineers to allow the garrison to make their sortie. A little further on in a bye-road there stood a commissariat waggon of the London Scottish, with a guard of half-a-dozen men smoking round their stacked rifles—a pretty little warlike "bit" for the photographer; but the hurrying, remorseless crowd prevented any possibility of taking it. We were glad to reach the prettily-decorated village of Cosham, and gladder still to get a glass of bitter beer, for we were coated with dust and as dry as if we had swallowed Paley's *Evidences of Christianity.*

The battle was to begin at twelve o'clock, and as we were anxious not to miss any of the slaughter we made a forced march so as to get on the ridge before that hour. There is not a finer natural theatre in the world than the Portsdown hill and the country around it, nor any place where such a large number of spectators can follow operations upon a large scale and grasp the drift of them. On one side beneath you is the village of Cosham and the little town of Portchester, with its historical castle, and on each side the broad stretches of Portsmouth harbour and Langston harbour. In the background lies the great Hampshire seaport itself, and beyond it the silver streak of the Solent, bounded on the horizon by the long, well-wooded shores of the Isle of Wight. On the other side the declivity is as sharp, and the spectator looks down on an undulating, fairly open country, rolling away for some twelve miles to Butser Hill and the Petersfield district. The main roads stand out like lines of chalk—as, indeed, many of them are—upon the landscape. Both views, to the north and to the south, make splendid photographs, but we had already done them justice and were in quest of rarer game.

To understand anything about the manœuvres it was necessary to have a highly-trained imagination. To grasp them thoroughly argued an immense power of fancy, only to be obtained, as one of my companions declared, by the aid of stimulants. The great forts which line the summit of the ridge, and command the country round for miles, are to be supposed not to exist. This is out of consideration for the wives and families of the invading army. Then the sea is also abolished and put out of the question. For the day Portsmouth was an inland town, defended by a garrison of some two thousand men. A reinforcement of four thousand or so are on their march from the westward to strengthen the place. An enemy, however, numbering ten thousand or so, comes down from the north in a highly-reprehensible and vindictive manner, and interposes itself between the town and the relieving column, and endeavours to prevent its getting into the town. This was the cause of all the trouble.

Looking down at the wooded country to the north and west it was difficult to believe that some fifteen thousand troops were within a radius of a few miles. The mystic hour of twelve arrived, and whereas we civilians had fondly imagined that that moment would be the signal for a roar of firing, for hidden troops to rush out of ambuscades, and for a general lively time, to our intense disappointment nothing whatever occurred. The landscape was as placid as before, and not a human being to be seen in the north valley except an occasional staff officer or umpire galloping furiously along.

Presently a couple of Middlesex Yeomanry, with their carbines unslung, came trotting along the ridge, followed by twenty or thirty of the same corps. These were the extreme advance guard of the northern force. Almost at the same moment a brass-helmeted body of men, looking like a mounted fire brigade, came galloping up from the other direction. These were the scouts of the western army. There was the material for a pretty little cavalry skirmish, and the crowd's flesh began to creep; but no gore was shed, for the Middlesex men scampered back to their supports and the Hampshires dismounted and occupied some broken ground in mounted infantry fashion. We tried a plate over this manœuvering of cavalry, but it was not a success. The dim weather necessitated a somewhat long exposure, and it was no easy matter to keep our camera on its legs, or to get a clear foreground in front of the lens.

By this time there was a glitter of arms away to the eastward, and column after column of troops—black, grey, and red—appeared in sight marching up the valley, with a double line of skirmishers in front of the leading brigade. This was the attacking force. Their advance was directed towards the relieving or western army, but a rattle of musketry in the distance showed that the garrison had made a *sortie* and were engaging the flank of the invaders. At the same moment the head of the western force began to appear near Fort Southwick, and very shortly the skirmishers of both sides were hard at work. The sight in the valley now was a pretty one. Two long lines of smoke showed the position of the hostile skirmishers. Behind these on both sides were regiments hurrying up in open order to join in the fray; behind that again was the main body coming up in columns of companies, while the cavalry, finding the situation becoming somewhat warm, were slowly retiring. We would have found it impossible owing to the crush to have done any good work was it not for the kindness of a sergeant of mounted engineers, which corps was keeping the ground. Seeing our difficulty, he very kindly allowed us to come outside the line of demarcation, and so to work without having the apparatus broken or being elbowed off our legs. In this way we succeeded in getting a series of plates of the proceedings; but, as I have said, the weather was against any very brilliant results.

In the meantime there were terrible doings in the valley. The fighting line of both sides had been strongly reinforced, until it had absorbed the greater portion of either army. These two long lines were blazing away at each other with the greatest *sang-froid*, at distances which varied from fifty yards to two hundred. Occasionally a regiment would rise and make a rush forward or backward in a way which would have entailed a premature interview with their Creator had it been done in actual warfare. The reckless hardihood of these men was almost incredible. They were too brave to lie down, so they strutted about regardless of rifles and Nordenfeldts, with a cool contempt of danger which came like a revelation upon one of my companions, who had seen some real hard fighting in his lifetime, and who bore in his waistcoat pocket a certain piece of bronze called the Victoria Cross—as honestly earned as ever a decoration was. "Why," he remarked, "there wouldn't have been any of them left at all. They would have been utterly annihilated;" and we forthwith began planning out graveyards and arranging for the decent interment of the belligerents.

So far we had, all things considered, no reason to be dissatisfied with our day's work from a photographic point of view. When the "cease firing" sounded, however, and the march past was about to begin, we found the crowd so dense about the saluting point that photography was not only out of the question, but it was absolutely necessary for us to abandon our apparatus if we wished to see anything ourselves. Handing it over, therefore, to the care of a friendly sutler, we elbowed our way through the crowd—there must have been more than a hundred thousand people on the side of the hill—and eventually secured a position not very far from the staff, where were the Duke of Cambridge, Prince Edward of Saxe-Weimar, the popular Governor of Potsmouth, and many others of light and leading, including the French military *attaché*—a gaudy warrior in red trousers and sky-blue coat, who seemed, to judge by his expression, to think very small beer of our citizen army.

The march past began with the scanty force of yeomanry, and then for rather over an hour regiment followed regiment until the whole had gone by, some of the principal ones being cheered by the crowd. The local Hampshire corps, some eight hundred strong, went by in the opinion of experts in better style than any of the metropolitan regiments, which may be explained by the fact that belonging to a military town they have constant opportunities of imitating and competing with the regulars. The Victorias, the Artists, the London Irish and Scotch, the Westminsters, the Second Sussex Artillery, the Inns of Court, and the Tower Hamlets all did well. The Nordenfeldts—grim-looking machines, pulled along in the rear of the Victoria Rifles—created considerable curiosity among the crowd. "What's them?" asked one fellow near us. "Them's the regimental cookin' apparatus" another answered, with a look of superior wisdom. "For cooking the enemy's goose" we ventured to suggest, but that joke fell upon barren ground and was lost. Taking them all in all the general opinion seemed to be that, though there were a good many weedy men in the ranks, the average of physique was very fair—undoubtedly superior to that of most of the present short-service regiments.

There was one episode in the fight upon Saturday which was somewhat amusing. Among the defenders there was a troop of the 4th Dragoon Guards—the heroes of the Kassassin charge—and these slashing horsemen took a great delight in chasing and chevying any of the opposing yeomanry who came near them, thinking, no doubt, that it was capital fun to take a "rise" out of these amateur soldiers. One innocent-looking yeoman, after this game had been going on some time, rode straight towards the dragoons, and then, as if surprised at finding himself in the jaws of the lion, turned and fled. Away clattered the whole troop in hot pursuit, and rode right into a nice little ambuscade prepared by the Westminster Rifles, where they were all made prisoners. The innocent-looking yeoman had been a decoy duck, and the crestfallen dragoons rode back, sadder and wiser men.

With the conclusion of the march past the proceedings terminated, and the various regiments began to file off the ground in different directions. Our sutler had moved off with his cart containing the camera and carriers, and it took an hour's seeking before we discovered him. However, at last we unearthed the delinquent and recovered our invaluables, after which we turned our backs on the battle-field, where the carrion crow was already flapping its heavy wings over the empty ginger-beer bottles, and struck out for home.

Just outside Cosham we overtook an omnibus, which, for a wonder, was not full. We said nothing, but looked at each other. Should we be partners in bolstering up this monopoly—this indefensible overcharge? We had spent the last week in denouncing it. Were we to submit to it now? We got inside the 'bus while we were turning the question over in our minds, and arrived at Portsmouth before we had been able to come to any definite conclusion. A. CONAN DOYLE, M.B., C.M.

THE ROYAL INSTITUTION.

A LECTURE BY PROFESSOR DEWAR.

ON Thursday, the 15th instant, Professor Dewar, in the course of a lecture at this Institution on *Flame and Oxidation*, showed that platinum black would liberate iodine from iodide of potassium.

Professor DEWAR threw some platinum black into a solution of iodide of potassium and starch, and the liquid was coloured blue by the iodine thereby liberated. He stated that this was due to the oxygen which the platinum black carried down with it, and showed that platinum black taken from under boiled water to first get rid of its oxygen had not the same effect. By the same power platinum black oxidises alcohol into acetic acid. Professor Dewar also stated that the oxygen gas liberated by the leaves of trees under the influence of light does not appear to be ozonised. The enormous heat of burning magnesium is just strong enough to partially decompose carbonic acid; but how the leaves of trees do it under the influence of light is a mystery. The red rays of the spectrum are most active in setting up the decomposition by the leaf, and the action of sunlight is clearly a deoxidising one. The carbon is not deposited in a pure state, otherwise it could not be carried into the plant. It seems to be produced in the first instance as sugar, which afterwards changes to starch, or possibly starch is produced first and sugar afterwards. Starch cannot be carried about in the plant; hence the inference is that sugar is produced first. He then exhibited the liberation of carbonic acid gas from a liquid, under the action of the light from the electric lamp, but did not say what the liquid was.

DR. ODLING ON CURIOUS PROPERTIES OF HYPOSULPHITE OF SODA.

Last Friday evening Dr. William Odling, F.R.S., lectured at the same Institution on *Oxygen in Water*. Sir Frederick Bramwell occupied the chair. Among the listeners were Professor Tyndall, Mr. William Crookes, various other men of science, and a few members of the nobility. The auditory was a fairly large one. In the course of his lecture,

Dr. ODLING said that 100 volumes of water at 0° C. dissolve 4·11 volumes of oxygen, and at 15° C. dissolve 2·99 volumes. Bunsen was the first to determine this. At 0° C. 100 volumes of water dissolve 6886·10 volumes of sulphurous acid, and at 15° C. 4356·40 volumes; at 0° C. 114800·00 volumes of ammonia, and at 15° C. 78270·00 volumes. In some way these gases are reduced to the liquid state in the solution, and the bulk of the original water is thereby increased. At 45° F. one gallon of water dissolves 2·199 cubic inches of oxygen gas, and at 70° F. 1·797 volumes. By weight, water contains about four grains of oxygen per cubic foot in summer, and five grains per cubic foot in winter. Variation of barometric pressure causes a small fraction of a grain difference of oxygen in each cubic foot of water. Although these proportions may seem small, the quantity of liquefied oxygen carried in water in a short time over Teddington Weir, on the Thames, can be reckoned by tons. It oxidises the sewage lower down to some extent; consequently the oxygen in river waters tends to keep the streams pure and sweet. In explaining the methods now adopted by chemists to estimate the amount of oxygen in river waters he (Dr. Odling) said that hyposulphite of soda or of lime is used, but not exactly the hyposulphite of soda used by photographers, which is in reality thiosulphate. The salt used by him bleached the ammoniacal solution of copper, and deoxidised indigo, magenta, and iodide of starch. He showed, by experiment, that a solution of white indigo turned blue when mixed with water containing air, and that when a solution of hyposulphite of soda is added to such blued water it has the choice of deoxidising either the indigo or the air in the water; also that it deoxidises the water first, after which it decolourises the indigo. Thus the quantity of hyposulphite of soda added to the water before it decolourises the blue indigo bears a direct relation to the quantity of oxygen in the water, and affords a means of estimating its amount. In one experiment he (Dr. Odling) added just enough hyposulphite of soda to decolourise the liquid, and then poured it from one glass vessel to another. In its passage it took up oxygen from the atmosphere, and, consequently, fell into the second vessel as a blue liquid—a striking result which "brought down the house" in the way of applause. The lecturer then gave the results of various analyses of the water of the Thames, in relation to the proportion of oxygen it held in solution. At Richmond it had nearly its proper quantity, and as it came into contact with sewage the quantity gradually decreased. In London the quantity was very low, and off Erith the water contained but half a cubic inch of dissolved oxygen instead of two cubic inches per gallon. Near the mouth of the Thames the proportion of oxygen rose again to within ten per cent. of its proper amount. Although river water is a very weak solution of oxygen it must be remembered that it also contains but a small amount of sewage in proportion to its volume. Oxygen thus renders harmless a proportion of the sewage; but it is not certain as yet whether, in river waters, it destroys those minute living organisms which are the germs of certain diseases. On this point the opinions of scientific men at present differ greatly.

PRODUCING PRINTING BLOCKS BY MEANS OF PHOTOGRAPHY.

THE following is the provisional specification of Mr. W. B. WOODBURY.—*Dated October* 5, 1883.

My invention relates to surface blocks by the aid of which typographic prints may be obtained in the ordinary printing-press, and it has for its objects novel methods of giving to photographic negatives or positives the necessary qualities to produce from them such surface printing blocks.

These qualities have usually been obtained by breaking up the continuous half-tone of the negative or positive produced in the ordinary way by photography into a series of lines, simple or crossed, dots, or grain similar to that produced by a lithographic stone or by effects similar to network or gauze. From negatives or positives so produced printing blocks have heretofore been obtained either by making reliefs in the well-known way and pressing such reliefs into the surface of metal, or by transferring to zinc and then etching; also by exposing negatives so produced over a sheet of zinc covered with a substance having the property of becoming insoluble by the action of light, such as bitumen, or gelatine and bichromate of potash, and after removing the soluble parts etching the parts left bare. These processes are and have been for some time in ordinary use, and my invention consists in new or improved methods for the production of negatives or positives suitable for the purposes above described.

In order to put my invention in operation, I procure a series of negatives or positives from such objects as fine ruled lines, netting, gauze, dots, or a print from a grained stone. I use these as "resists" from which I make in the ordinary way what is well known as a carbon transparency, and I transfer the same by the ordinary method to the negative or positive and by then washing away the soluble portions I give them the necessary qualities. Or, sometimes I make a photolithographic transfer and I transfer the same to the negative or positive, and if sufficient density is not obtained I dust bronze or other opaque powders over the image, so increasing it in force.

In another method which I sometimes adopt, by means of what is known as the dusting process, I coat a sheet of glass with a compound of gelatine or albumen, grape sugar, and bichromate of potash, and after exposure under a negative or positive I sift over it suitable granular powders, or the material used for flocking paper, thus producing a grain negative or positive suitable for the purposes already described, or I coat a negative or positive with the same solution, and I treat it in the same way as the plain glass.

Or sometimes by means of what is well known as the Woodbury process I make a relief image from the combination of the negative or positive and any of the various resists mentioned, and by rolling or other convenient pressure I make a reverse relief of the same in a sheet of enamelled or glazed cardboard. This image I ink over carefully with an ink roller, and I transfer in the ordinary the image so produced to zinc for etching, or to stone for lithographing.

Or sometimes I take a gelatine relief, developed on glass by the Woodbury process in the usual way, and, having warmed the relief, I pour over it melted wax, paraffine, or similar suitable material, and on this I lay a sheet of plate glass, previously greased and warmed, and after squeezing out the superfluous wax I allow it to cool. When set I detach the glass, leaving a smooth and even surface of wax filling up the hollows of the relief. Over the surface so prepared I pass backward and forward a fine, flexible, and elastic V-shaped tool in the same way as in an ordinary planing machine, the tool cutting deeper or shallower lines according to the depth of the wax; the same operation is then performed in a transverse direction, giving a series of cross-lines varying in depth and thickness, and from this I take an electrotype, from which I take a second one, which forms the printing matrix.

APPARATUS FOR EXPOSING SENSITISED PHOTOGRAPHIC PLATES OR FILMS.

THE specification of Mr. JOHN EDWIN ATKINSON, of Greenwich, for the above invention is as follows:—

My invention relates both to indoor and outdoor photography, and consists in improved means or apparatus for holding and protecting sensitised dry plates or films either for transit or storage, and for enabling the plates or films to be readily placed in position for exposure in the camera and removed therefrom after exposure in open daylight, whereby a number of such plates or films are rendered more conveniently portable than in ordinary double backs, changing-boxes, or other costly and inconvenient apparatus as heretofore constructed.

My invention consists in the employment of envelopes made of cardboard, *papier maché*, or other light and cheap material in the form of a square or rectangular frame, constructed to carry one or two plates or films (preferably one plate or film only), having an opening at front rather smaller than the plate or film to be carried. This opening of the frame is closed by a sliding shutter, preferably flexible and sliding in grooves or otherwise, and the plate or film is introduced at the back of the envelope (when constructed to carry one plate or film) by being laid therein, face downwards, and the envelope is merely closed at the back by four loose flaps respectively attached to its four sides and merely folding down over one another, or by other suitable means whereby a light-tight closure is ensured.

The plates or films are carried preferably each in its own envelope, and the camera is provided with a "back," being a receptacle or box which is adapted to fit against the back of the camera, and is hinged thereto or fitted in slides thereon so as to be readily moved in and out of position to enable the operations of focussing and exposing to be expeditiously performed. This box or receptacle is of a size to exactly contain one envelope; it has an opening at front corresponding to that in the envelope, and a door at back at which the envelope is introduced, and a slot at one side to enable the slide or shutter of the envelope to be withdrawn.

The operation is as follows:—The envelope containing the plate is placed in the box or receptacle, the projecting portion of the slide or shutter of the envelope being passed through the slot in the side of the receptacle. After focussing the picture in the usual way the "back" is placed in position for exposure, and the shutter or slide of the envelope is drawn out through the slot in the "back." After the exposure is terminated the shutter is pushed in and the envelope removed from the "back," the exposed plate which is still contained therein being subsequently developed at leisure.

The focussing-screen is hinged to the camera, and the hinges are so constructed that the screen may be folded against the rear of the "back" in packing the camera for transport.

[The final specification is illustrated with three sheets of drawings, showing in what manner it is proposed to carry the invention into effect. We are led to inquire if the patentee be aware that dark slides or "envelopes" formed of paper, together with frames by which to adapt them to the camera, have for some time been manufactured and more or less extensively employed in this and other countries?—EDS.]

CHANGING BOX AND DARK SLIDE COMBINED. By Dr. HEINRICH KAYSER, of Berlin.

My invention relates to the construction of photographic exchange boxes, the object of which is to permit the removal of the exposed plates and to bring a fresh plate in its place in full daylight, without being compelled as heretofore to slide the box or case into a second case in order to be able to effect the said manipulation, *id. est.*, the exchange of a fresh plate for the exposed plate.

By employing my construction of exchange boxes I am able to exchange a series of twelve to fifteen plates when glass plates are employed, and expose them consecutively.

The front or foremost plate lies just behind the slide in suitable position for exposing, and is, after being exposed, withdrawn and placed behind the other plates which have not been exposed. For this purpose one end of the box or case is made to act as a door, so that the exchange can be readily effected by inserting the hand; as, however, the plates must be entirely withdrawn from the box or case, and it is necessary to exclude the light, I employ a sleeve of suitable material, capable of excluding the light, which is slid or pushed over the arm of the operator. A suitably-arranged spring or springs presses or press against the movable partition or false bottom of the box or case, and hold the series of plates firmly against each other when the outer or foremost plate is to be exposed, whereas a device is provided so that the pressure of the spring can be removed, and so that the plates rest loosely against each other and can be readily exchanged.

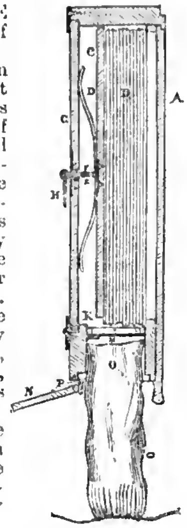
The accompanying drawings represent my improved exchange box or case in section.

A is the slide for closing the box or case, behind which the plates B, which are to be exposed, are arranged so that they rest against the frame of the box or case.

The single plates are separated by an intermediate layer of black or other paper through which the light cannot penetrate, which said layer is loosely attached to the back of each plate. The plates B are continuously pressed against the bearing surface of the frame by means of a suitable spring acting on the movable or false bottom, so that the front or foremost plate is kept in focus.

I represents the side of the box or case which is formed to act as a door, which said door lies snugly against the two ledges or rails K and L, and is movably connected with the box or case by means of a piece or strip of canvas, leather, or other suitable material which is glued or otherwise attached to the box or case frame and clamped tight by means of the ledge K or a suitable joint; hinge or hinges can be employed to the like purpose.

The ledges K L serve also to hold the sleeve O of suitable fabric which will exclude the light, which said sleeve can be folded up and carried in the space M of the box or case between the door I and the outer door N, to the exchange box or case, which said door is provided with suitable hinge or hinges I. The requisite play for enabling the plates to be readily exchanged, is attained by drawing back the false bottom or partition C towards the bottom of the said box or case, thereby compressing the spring or springs D, which can be effected by connecting a rod or spindle E to the false bottom C, which said rod E is provided with a suitable knuckle or other joint F and reaches through the bottom G of the box or case. The outer end of the rod E is provided with a ring H, so that by pulling this ring outwards the joint F is drawn to the outside of the box or case, the spring D compressed, and space or play for the exchange of the plates in the said exchange box attained, whereby the false bottom C can be retained in the position mentioned above by simply giving the outer end of the rod E a partial revolution of 45° around the knuckle or other joint, so that the said outer end of the rod E lies flush, or about flush, with the bottom or back of the box or case.



As soon as the exchange of the plates has been effected the rod E is returned to its original straight position by means of the ring H, whereupon the plates are again firmly compressed by the intervention of the false bottom C and the spring D. My improved exchange box or case for photographic plates possesses, in comparison with the ordinary exchange boxes, not only the advantage of the enormous reduction in weight, but also of being able to employ plates of various sizes; for which purpose it is only necessary to insert a suitable, adjustable, or readily removable ledge to lessen the length or width of the said box or case, but so as to leave the space next the door I free. My said improved box or case can be employed for the ordinary dry plates, but is specially adapted for dry plates in which the emulsion is not attached to glass, but to a thin flexible plate of suitable material, such as have already been the subject of various patents.

The photographic exchange box, as shown in the accompanying drawing, can contain about fifty of such said flexible plates, and when such said plates are about eighteen centimetres wide and twenty-four centimetres long, weighs, inclusive of the plates, only about four pounds.

The back or bottom of the case is also provided with suitable hinges to facilitate the introduction of the plates into the box.

Having now described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is—

1. The construction of a photographic exchange box or case, in which the plates can be changed in full daylight by employing a suitable sleeve O, of a fabric which will not permit the light to penetrate the same, thus rendering the employment of an extra case unnecessary, whereby the said box or case consists of the bottom or back G arranged to open on suitable hinges, the slide A, the movable false bottom or partition C, which said false bottom and with it the plates are pressed forward by means of a suitable spring or springs D, so that the plate to be exposed is pressed snugly against its seat in the frame, and of the door I formed in the one end or side of the said box or case substantially as described and shown in the accompanying drawings.

2. The movable false bottom C is provided with a rod E, which said rod has a knuckle or other joint F at about the centre of its length, and a ring H, or its equivalent, at the outer end, so that when the ring H to the said rod is pulled outwards the rod E is drawn out through a boring in the back or bottom of the box or case, the spring or springs D is or are compressed, the false bottom drawn back and the plates given free so that the exchange can be made, for which purpose the rod E is turned on its knuckle or other joint F and the false bottom held in its rear position, whereby the arm of the operator must be inserted in the said sleeve O of impenetrable material or fabric, substantially as described in foregoing specification and shown in the accompanying drawings.

3. The combination of the door N to the space at the end of the box or case to receive the sleeve O, with the said sleeve of light-excluding fabric O, and the door I to the inner space of the said box or case, substantially as described in the foregoing specification and shown in the accompanying drawings.

4. The general arrangement and construction of the parts of my improved photographic exchange box or case substantially as and for the purpose set forth in the foregoing specification and shown in the accompanying drawings.

Improvements in Obtaining Relief Printing Surfaces.

Abstract of Specification. By Henry Rafter, Artist, Lee, Kent.

The principle of this invention, the prior conception of which I claim, consists in combining "process" for relief printing surfaces with "wood engraving."

In the first place, the surface of an ordinary wood block, metal plate, or other suitable surface, undergoes a preliminary engraving either by machinery or hand, whereby it receives certain "tints and grounds" required for a proposed drawing or work of art.

After the surface of the block has been thus treated, the object of the process for relief printing surfaces is to raise up and create in these furrows and cavities, left by the preliminary engraving, certain matter, substance, or material, which being artistically disposed and distributed over the block will, in conjunction with the said "tints and grounds," represent in "proofing" the outlines, shadows, and general features of the drawing or work of art.

The "lights, clearing, and cleaning," are then executed by engraving.

I make use of, in part, of the process already patented in the two following expired patents as a factor in the practicability of my invention.

A.D. 1860, September 21, No. 2309. An improved mode of producing relief printing surfaces.

A.D. 1864, September 15, No. 2641. Producing relief printing surfaces.

The furrows or cavities already mentioned as being left between the ridges or reliefs by the preliminary engraving of the "tints and grounds" are filled, under pressure, with a material such as pulverised chalk, oxide of zinc, &c., which is forced into an exact level with the top of these ridges or reliefs, producing a "prepared surface" apparently similar with the original surface of the block uniform and polished.

This "prepared surface" is then ready to receive the "artistic work," which will principally consist of the outlines, shadows, and general features of the drawing or work of art, as distinguished from the "tints and grounds."

This is either drawn direct on the prepared surface or transferred, photographed, or otherwise projected on it, inks or other suitable mediums being used, which, wherever applied, will harden or protect the surface of the material pressed into the cavities.

The rest of the material in the cavities, not having its surface hardened or protected, can then be brushed or wiped away; whereupon the "tints and grounds" will appear in equal relief with the "artistic work" represented by the hardened or protected parts, the "tints and grounds" terminating, or rather being merged, in the "artistic work" wherever the latter crosses or covers them.

A thorough hardening of the material left in the cavities can now be made, with either fluid silex, wax, varnish, or any suitable medium.

If the "artistic work" is executed by "etching," intaglio engraving, photolithography, photozincography, or similar methods, it is necessary to procure an impression of the same in transfer ink on transfer paper, then coat the impression with an adhesive medium and lay it on the "prepared surface" under pressure until the adhesive medium has dried. Damp and remove the transfer paper, leaving the impression in transfer ink on the "prepared surface;" this ink will protect those parts that are not to be removed in the subsequent brushing or wiping. In this last operation the "material" will require damping.

By the means of the well-known effect of light acting on a film of gelatine sensitised by bichromate of potash, I spread a sensitised film of gelatine on the "prepared surface," and exposing it under a negative obtained from the "artistic work." I retain the parts acted on by the light, by brushing away after damping the film and "material" unacted on, thereby leaving the "artistic work" in equal relief with the "tints and grounds."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 15th inst., the chair was taken by Mr. F. W. Hart.

A letter from Mr. F. C. Beach, of the *Scientific American*, was read. Mr. Beach stated that an Amateur Photographic Society was in course of formation in New York—the first of the kind in that city—and suggested an interchange of correspondence between the new Society and the London and Provincial Photographic Association.

The suggestion was approved, and it was considered that it would be best carried out by an interchange of copies of minutes. The Secretary was directed to write to Mr. Beach on the subject.

The death of Mr. H. Baden Pritchard, so well known and esteemed in photographic and literary circles, and a member of the Association, was referred to by the Chairman and several of the members, and a letter of condolence was ordered to be sent to the relatives.

Mr. W. M. Ashman inquired whether any of those present had tried "golden fabric" as a medium for dark room use.

Mr. A. Cowan replied that Mr. Mackie had, at a former meeting, given favourable details of his experience of its use.

Mr. A. L. Henderson showed a plate box made of tin. The grooves were intended to hold two plates each, and were formed of a single thickness of tin bent at a right angle and soldered to the side of the box. The entire thickness was much less than that of a box fitted either with paper or wooden grooving.

Mr. W. E. Debenham thought it objectionable that there should be sharp edges of tin, which would be apt to scratch the edges of the plates. If the grooving were made of thin sheet tin folded it would take scarcely any more space than in the box shown, and could be soldered against the side more quickly than the five separate strips could.

Mr. Henderson did not mind the scratching of the edges of the plate, and preferred the single thickness of tin.

Mr. Cowan said that with folded tin plate the metal need be only half the thickness of that in the box shown, and would then take up no more space.

Mr. Ashman remarked that particles of iron would cause black spots on the plate. These would be more likely to be given off from the raw edge of the metal than if it were folded.

The Chairman inquired whether, if plate and particles were both dry, there would be any action.

Mr. Ashman replied that there was difficulty in entirely removing particles from the surface of a plate, and if carried into the developer they would act, of course.

The Chairman said that he had recently made many inquiries as to how to avoid spots which appeared to be caused by particles on the surface of plates. He had suggested the use of chamois leather for wiping plates before exposure and development, and it had proved successful.

Mr. HENDERSON remarked that a pupil of his had had many failures from spots in plates, coated with emulsion, which he had prepared. The cause had been traced to a tube of grey india-rubber that had been used for the water supply; particles of sulphur were given off.

Mr. COWAN said that red or black rubber should always be used for the purpose.

The CHAIRMAN added that the cheaper kinds of red rubber were almost as bad as the grey.

Mr. HENDERSON said that a large professional plate-maker had used red rubber as a roller for coating, but had to abandon its use on account of the spots caused by it.

A question was read—"Why does a boiled emulsion fix out more than one prepared with ammonia?"

Mr. DEBENHAM said that this question was one of an objectionable kind, as it assumed something to be a recognised fact which had yet to be established.

Mr. COWAN remarked that the question should be—"*Does* an emulsion prepared by the boiling process lose more in fixing than one prepared with ammonia?"

Mr. HENDERSON said it was a fact that boiled emulsions did fix out more than those prepared with ammonia. He had prepared many emulsions both ways, and could speak decidedly.

Mr. DEBENHAM inquired whether in Mr. Henderson's experiments he had used the same quantity of iodide when making a boiled emulsion, and when using ammonia.

Mr. HENDERSON replied that he used eight times as much iodide when boiling as with ammonia.

Mr. DEBENHAM asked whether in that case the question might not as fairly be—"Why do plates containing a large quantity of iodide fix out more than those made with a small quantity?"

Mr. HENDERSON believed that when a large excess of soluble bromide was employed the iodide of silver was reconverted into bromide. He thought from the fact that the plates he spoke of were quickly fixed they did not contain a large quantity of iodide of silver, although a considerable quantity of soluble iodide was employed in making the emulsion.

Mr. COWAN produced two plates cut from the same plate originally, which had been exposed under Warnerke's sensitometer. In the one case, however, the plate had had three successive illuminations to the phosphorescent tablet; but it did not give numbers on the sensitometer indicating more than twice the sensitiveness or exposure. He thought it better, when using plates of high sensitiveness, to give only half the exposure rather than rely upon the higher figures of the sensitometer.

Mr. HENDERSON stated that there was a great difference in the intensity of sensitometers, some giving a higher number than others with the same plates.

Mr. A. MACKIE said that a gentleman had that day told him that he used with success the "leucine" solution in making emulsion, but had made a variation by allowing the silver to precipitate from it, pouring it off, finishing as in the precipitation method advocated by Mr. W. K. Burton.

Mr. HENDERSON said that that plan might prove very successful if the solution were used as it was, instead of being diluted with water, and in that case the same solution would, after filtration, serve repeatedly and be all the better for the accumulation of nitrates.

Mr. C. Ray Woods was elected a member of the Association.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board held their monthly meeting on Wednesday, the 7th instant, at 181, Aldersgate-street.

The minutes of the previous meeting having been read and confirmed, Mr. G. Haupt was elected a member.

This being the first meeting of the Society since the decease of their Vice-President, the Rev. F. F. Statham, a letter of condolence was forwarded to Mrs. Statham.

The next meeting will be held on Wednesday, the 4th June, at 8 p.m.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE last ordinary meeting of the session was held in the College of Physical Science, Newcastle-on-Tyne, on Tuesday, the 13th instant,—Professor Bedson, D.Sc., occupying the chair. Messrs. W. C. Fletcher, P. Hall, and A. D. Fisher were elected members.

Professor HERSCHEL, M.A., &c., then delivered a lecture on *The History and Results of Improvements in Photographic Lenses*, which was followed with close interest by a good muster of members. Professor Herschel related particulars of the first aërial telescopes of long focus, and explained the principles of correction of chromatic aberration of single lenses by which Hall and Dollond, at the middle of the last century, and Dr. Blair, produced compound objectives of two-feet focus equal in magnifying power to the single lenses of 60- to 120-feet focus made and used by Huyghens. The non-agreement of the focus of red rays with that of blue rays in a single lens was illustrated with the lime light, as well as the different positions in the same lens of the foci, towards which it collected rays passing through it respectively near its centre and near its margin. The removal of this second defect, or spherical aberration of objective lenses, is connected with the subject of increasing the angle and flatness of field, and of lessening distortion of the image in modern combinations of photographic lenses. As it embraced a much wider class of corrections than that performed by methods of achromatising, further explanations of it were reserved; and, if another opportunity for describing them should occur, it would form the subject for a future lecture.

The CHAIRMAN proposed, and Mr. J. P. GIBSON seconded, a vote of thanks to Professor Herschel, which was carried.

Six photographic prints, size 18 × 16 downwards, were then balloted for and duly handed over to the successful members. These pictures were given by Mr. Ed. Geold and Mr. P. M. Laws. The former gentleman also presented a few to the Society.

Mr. Wm. Ridley was appointed Curator to the Society's album and portfolio, in place of Mr. Kemmish, resigned.

The Hon. Secretary showed an universal camera having revolving bellows and great length, the half-plate size extending to sixteen inches, and very light and portable; also, two of Guerry's pneumatic shutters (sent by Messrs. Proctor and Sons, of Newcastle). These were examined with much interest by members, and attracted general approval.

The meeting was then adjourned.

LEEDS PHOTOGRAPHIC SOCIETY.

THE ordinary monthly meeting of this Society was held on Thursday, the 1st instant,—Dr. Thorpe, F.R.S., in the chair.

Messrs. Dennison and Hirst were elected members of the Society.

Mr. C. H. Bothamley, F.C.S., then read a paper entitled *Some Experiences of a Beginner*. [See page 327.]

Mr. WASHINGTON TEASDALE, F.R.M.S., referring to Mr. Bothamley's remarks respecting the use of canary medium, said that, so far as he was personally concerned, he much preferred the use of that medium, and he had used the most sensitive plates in the market; but, by carefully shielding the plate during development, he could produce negatives free from all trace of light fog.

Mr. T. W. THORNTON (Hon. Secretary) said Mr. Bothamley spoke very favourably of the use of sulphite of soda. Some little time ago he had obtained from the Platinotype Company some of their sulpho-pyrogallol, but did not notice any benefit arising from its use. Since then, seeing the very favourable notices in the Journal, he had made up a solution by the formula given by Mr. A. Pringle, and, although it worked well immediately after preparation, in the course of a short time it would not develope a fully-exposed plate in any less time than forty minutes, and then the resulting negative was of a deep yellow colour. He knew of several members who had tried the same formula, and all had the same experience. This striking difference in results led him to suppose that the sulphite of soda used by him must be of a very different nature to that used by Mr. Pringle. He would add that both the solution made up by him and the one obtained from the Platinotype Company had turned a deep claret colour after standing for a few days.

Mr. TEASDALE said he had noticed the same appearance in the colour of the sulpho-pyro. solution, and in his hands it was most prolific in giving green fog.

Mr. F. W. BRANSON suggested the use of an American clock for timing the exposure given by an instantaneous shutter—first removing the pendulum.

The CHAIRMAN gave the results of an inquiry as to the changes brought about by adding alum to the ordinary hypo. bath.

Mr. H. RODWELL exhibited a series of views taken in Cork and the neighbourhood.

Mr. TEASDALE exhibited some platinotype prints and lantern transparencies from "instantaneous" negatives recently taken by him of moving objects, some plates being developed by pyro. and others by hydrokinone. He called attention to the general clearness and absence of light fog, in connection with the fact that all the plates were developed by the light of his usual lamp of canary medium, and that while printing the transparencies on plates of only moderate rapidity (nominally ten times) he had indulged in the warmth and extra light of a Fletcher's open gas fire in a small operating-room about ten feet by eight feet. Mr. Teasdale also exhibited two negatives which, on being put into the ordinary clearing bath of alum and citric acid, had immediately become overspread with a crystalline formation of most unusual and peculiar character, appearing under the microscope like a longitudinal section of vegetable tissue with fusiform cells circularly dispersed around the nuclei. These crystals gave no colour under the varied conditions of polarised light, which may have been due to the crystalline deposit being too thick.

NOTTS. PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Association was held on Friday, the 9th instant, at the Morley House, Shakespere-street,—Mr. G. Shepperley, President, in the chair. There was a very good attendance.

The CHAIRMAN spoke on the rise and progress of photography in Nottingham, and the difficulties that had been encountered through various obstacles, but which had been successfully overcome. He advised the members to study nature as much as they could during their trips in the coming summer, for the more they indulged in such study the more would it reveal itself in its true and interesting character.

Mr. S. BOURNE (President of the Nottingham Society of Art), in moving a vote of thanks to the Chairman for his address, said that the subject of photography was an interesting one, which could not be exhaustively dealt with in one paper; and the degree of excellence at which it had arrived had not been brought about by one, two, or three men, but by a little army of workers. He might say that he was the principal founder of the old Nottingham Photographic Society that had been in existence twenty-five years ago, but which had died a natural death through the removal of one and another. He heartily wished the present Association great success, which it was sure to have from the evidence he had before him of modern apparatus; and the rapid shutters kindly brought by the members showed an interest which, if retained, was an indication of great success. They, no doubt, had heard of the Fothergill process. Plates prepared by that process required a long exposure, compared with the present rapid gelatine plates. He might say it was due to him as a member of the Nottingham Photographic Society that the Fothergill process became so universally adopted; for, although the process had been made public, no one took it up practically. He, however, prepared four dozen plates by it, took them to the English lake district, and brought home forty-five good negatives. This was a great success in the early days of photography, and this success was made known by him in a letter which appeared in *The Times*. As a result of that letter he was deluged with correspondence from all parts—so much so that the postal authorities of Nottingham had to give the exclusive use of a post-bag to deliver the letters, which numbered something like 150 each post. It was impossible for him to sit down and reply to all, but he replied through *The Times*, detailing the particulars of the process, and, as a result of that letter, he had met gentlemen in India and elsewhere who successfully practised it. Beautiful as that process was it is now slumbering as a process of the past, and has given way to its rival, the gelatino-bromide process. The march of progress places its stamp upon all processes, and one by one gives way to that which is more excellent.

The motion, having been seconded, was carried *nem. con.*

The members proceeded to the investigation of the apparatus, &c., after which the proceedings terminated.

The next monthly meeting of the Association will be held on Thursday, June 12th.

Correspondence.

RAPID *VERSUS* SLOW DEVELOPMENT.

To the Editors.

Gentlemen,—In Mr. E. Brightman's paper on the above subject, read at the meeting of the Bristol and West of England Amateur Photographic Association, and reported in the Journal of May 9th, I see he omits sodic sulphite from his developer. As I am anxious to know *why*—more especially since none of the members present seemed struck by the omission—I should be obliged by the information through the Journal, should this catch the eye of Mr. Brightman.—I am, yours, &c., Curious.

May 19, 1884.

Notes and Queries.

W. Brown inquires if it will do any harm to a photograph on albumenised paper if it receive a coating of spirit varnish previous to its being painted upon.——In reply: We have a vivid recollection of similar treatment having been strongly recommended as a preparation for painting upon the photograph.

Donald Fraser says:—"I have some photographs I highly prize which were mounted on cardboard some years ago. Now I wish, if possible, to have them taken from their mounts and placed in a loose scrap-book. Can this be done? If so, how best can I do it?"——In reply: Place the picture in warm water for a few minutes, and a separation of the photograph from the mount can soon be effected.

W. says:—"In working instantaneous photography with rapid shutter I find the plates are, as a rule, considerably under-exposed. How would you recommend me to develope these plates?"——In reply: Let "W." adopt the formula given by Mr. H. Y. E. Cotesworth on page 310 of our issue of last week. If this do not effect the desired end, let him employ either more sensitive plates or a shutter that does not act quite so rapidly.

"Which is the denser, from the point of view of optical refraction—water or alcohol? And what relation do these bear to glass and other substances? Your reply will oblige, yours, &c., John P. Richards."——We reply that alcohol exceeds water in this respect—the former having 1·372 and the latter 1·336 as its refractive index. That of ordinary plate-glass is 1·540, which, however, is only approximative, as the refractive index varies with different samples.

"My studio is a ridge roof, having glass on one side only of the same, and glass down to within four inches of the floor on the same side—that is, the south side—consequently the sun is shining on it all day, and I have great difficulty in getting soft shadows. All the glass is covered with white blinds, and I have tried black over these at the sitter's end, but without much success. Will any readers help me by offering their experience or suggestions, which will be gladly tried by—Strong Light?"

A. McKinnell writes:—"I want to prepare some pellicle, and should feel much obliged if you would enlighten me a little by answering the following query:—After preparing an emulsion, if, instead of washing it when set, I were to pour over it enough alcohol to cover it, would the ammonium nitrate be eliminated from the emulsion as well as the water." ——In reply: By treating the emulsion with alcohol in the manner described the ammonium nitrate would be eliminated along with the water.

"I find that a portion of my studio which is much exposed, and which has to be put together with glue, gives me no end of trouble owing to the action of the weather. Can you suggest any means by which the glue may be rendered impervious to this atmospheric action? I have thought of alum and also of bichromate of potash, but ask your advice previous to adopting any decided steps.—Fred. Nelson."——In reply: Obtain some of the strongest Scotch glue and dissolve it in the smallest possible quantity of water, afterwards adding linseed oil and stirring well together. This is said to be very strong and well adapted for such a purpose as that indicated.

"The best remedy I can suggest to 'W. M. H.' is to glaze with ground glass (the ground face outwards) the whole of the sashes through which the wall can be seen *from the sitter's point of view*. He may try the effect by pasting tissue paper inside his present glass. If he can whitewash the wall it will add to the light. If the top light—that is, light from the sky—has not been reduced materially by the erection of the wall he will, I believe, be agreeably surprised at the result obtained by the use of the ground glass.—J. M. Young."

"To whom are we indebted for the first symmetrical lens employed in photography and what is the date of its introduction?—Historicus."——In reply: The first symmetrical doublet of which we have any account was described by Mr. G. Cundall in the *Philosophical Magazine*, in 1844. It was composed of single (or non-achromatic) meniscus lenses, one being mounted at each end of a tube, the length of which slightly exceeded the diameter of the lenses. This gives forty years as the period which has elapsed since the invention was first introduced.

E. U. inquires:—"1. Is it necessary or compulsory that unmounted copyright photographs should bear any words or notification to the effect of their being copyright?—2. If I buy an unmounted photograph at a shop or from dealers do I run any risk in copying it and selling copies, supposing there is no intimation of any copyright on it?"——In reply: 1. It is not necessary that a photograph shall bear upon it any announcement of the fact of its being copyright; hence—2. Any person who copies and sells under the circumstances described does so at his own risk.

Geo. Sanderson writes:—"One of the sides of the front lens of my large portrait combination has got a dark stain or series of stains over it. It does not seem to affect the definition; but I feel quite convinced that it must cause the lens to work much slower than it once did. Is there any method by which I can dissolve out the stain? I have rubbed it with precipitated chalk spread upon a soft wash-leather without producing any effect."——In reply: Mr. Sanderson must obtain some putty powder, and, having carefully and thoroughly washed his hands, dip the point of his finger first in water and then in the powder, and rub the stains very smartly with the finger thus prepared. This will effect their removal.

Lens writes:—"Are there any means whereby a tall person can be made to look shorter in a *carte-de-visite* full length? I fancy there are, but am not certain. I have tried tilting the camera, raising and lowering the front, &c. I have seen other people's full lengths, same size print, yet a larger face and plenty of room to spare at the top and bottom of the figure. I get distortion from somewhere."——In reply: If "Lens" has a studio of sufficient length he may with great ease reduce the photographic longitude of his tall friend to any required extent. Let him raise the camera (not the camera *front*) to a height nearly on a level with the breast or neck of the subject, and place it at such a distance as to give the required dimensions upon the focussing-screen. If, however, the studio be not sufficiently long to admit of this, then a lens of shorter focus must be obtained. If the camera be kept square—that is, without being tilted—our querist may depend upon obtaining a portrait in which there will not be any distortion, but everything in harmonious proportion.

Pembroke Marshall (New York), referring to a letter in our issue of February 15th, respecting the United States as a field in which to establish a lantern business, states that such an enterprise demands mature consideration before being embarked in, because (he says) "the price of labour here, the inferiority of native materials, and extortionate and almost prohibitory tariff on any foreign production render a mere comparison of English and American prices decidedly misleading."——We imagine that Captain Marshall, in speaking in a detracting manner of the quality of the "native materials" of his adopted country—such materials, at anyrate, as are requisite in the production of photographic transparencies and lanterns—does so with an insufficient acquaintance with these, as all photographers of experience attest the excellence of American chemicals and apparatus; and in this connection we do not perceive what other "native materials" are requisite, unless it be the glass and the paper for binding the edges. Neither do such specimens of brass and tinware (employed in lantern construction) as we have seen indicate the inferiority alleged. The high price of labour referred to is, doubtless, a consequence of the tariff on foreign productions; but with a more intimate knowledge of the lantern trade than our correspondent can be expected to have acquired he would know that the prices quoted in American catalogues leave, *to those who understand the business*, emoluments considerably in excess of what is hoped for by dealers on this side of the Atlantic, and this after making all allowances for high labour and prohibitory tariff.

Exchange Column.

Answers to Correspondents.

Correspondents should never write on both sides of the paper.

Photographs Registered.—

Frederick Argall, High Cross, Truro.—*Seven Photographs of Dr. Wilkinson, Bishop of Truro.*

John Thornbury, Brunswick-road, Gloucester.—*Photograph of Reredos in St. Michael's Church, Gloucester.*

William Lawrence Wildy, Dumfries House, Armley, Yorks.—*Photograph of the Interior of a Siemens' Furnace after Melting 2,000 Tons of Steel.*

Peter Davidson, Eglinton Photographic Studio, Eglinton Toll, Glasgow.—*Three Photographs of the English and Scotch Draught Team—One Photograph of the English, One of the Scotch, an One of Both Together.*

Dr. E. Liesegang, Ph.D.—Received: *Die Collodion-Verfahren* and *Der Silber-Druck.* In our next.

A. Z.—We shall bear the subject in mind, and may possibly devote to it an article or two on some future occasion.

Darkness.—Well-seasoned pine will answer quite well for a box for storing dry plates either before or after exposure.

F. F.—The crown masks and discs are only to be obtained through agents or dealers. The manufacturers do not supply them retail.

W. C. (F. Hill)—The stains appear to be due to the prints adhering together while in the hyposulphite bath. See answer to "P. P."

W. J. Blagden.—Your orthographic lens is incomplete if, as you say, the back compound consists of only one glass. No wonder it does not perform satisfactorily. You had better take it to the optician whose name the instrument bears.

F. S. L.—Better send us a negative or two to see the effect. From what you say, however, we surmise that light finds its way through the leather hinge and produces the effects of which you complain. Examine the slides carefully in strong sunlight.

Bartholomew.—You would do better to purchase the material than to make it yourself, unless you have some little knowledge of chemistry. We imagine that any photographic chemist can supply it. Messrs. Wratten and Wainwright, we know, keep it in stock.

Warwick.—Your best plan will be to advertise in the columns set apart for the purpose. Judging from your specimens, if they are a fair sample of your work, we should say you will have but little difficulty in obtaining employment as assistant operator at a moderate salary.

W. H. H.—The neutral sulphite rapidly oxidises into sulphate both in the crystals and in solution. The acid or bisulphite is more permanent, and, from the fact that it contains a larger proportion of sulphurous acid' is better, and retains its properties longer as an adjunct to the developer'.

Wm. G. Bateman.—The cause of the blurring is not that the exposure was not rapid enough, but that the camera moved during the exposure—perhaps from the jerk of the shutter. If you examine the negative closely you will find that the buildings and stationary objects are quite as much blurred as the moving ones.

S. J. Y.—If you read the article again you will see that, when the ivorine was simply soaked in cold water, and then applied, the picture was not allowed to dry first. If the picture be dried, then we advise its being made warm before the ivorine is squeegeed upon it. When this has been done perfect adhesion will, undoubtedly, be secured.

F. Ashton.—All will depend upon your ability. You must bear in mind that a business is not established and a good connection secured at once, some time being necessary for the purpose. Doubtless, if you advertise well, and issue good work, you will succeed. Possibly the vicinity of London would be the most desirable position in which to commence business.

Studio.—It is almost impossible to answer your query, as you have failed to include in your drawing any more than the actual roof of the house, and nothing below. If there be a room below what is shown in the sketch—say nine or ten feet high—then all you have to do is to put in a glass side; also remove a portion of the slates and substitute glass in their place.

P. P.—1. Imperfect fixation is the cause of the stains. Either the fixing bath was too weak in the first instance, or too many prints had been fixed in it. The stains may, however, have been caused by the prints sticking together while in the hyposulphite solution or in the first washing water.—2. The meaning is that with a large aperture the lens will cover the smaller size, and with a small stop the largest-sized plate.

G. Withers.—The marking on the varnished negative is due to the hyposulphite of soda not being thoroughly removed by washing; consequently it has crystallised out through the varnish. If a negative contain hyposulphite of soda no varnish will prevent its coming through to the surface.

G. E. L.—By merely looking at a sample of gelatine it is impossible to pass any reliable judgment on its merits for dry-plate making. All thin gelatines of the best kind are so much alike in outward appearance that we cannot say, from the examination of a piece a few inches square, who is the maker of the particular sample you enclose. This, however, we can say with certainty, namely, that this particular sample is one of excellent quality as a gelatine. As you do not succeed with it for dry-plate work try another sample.

Photographic Society of Great Britain.—The next monthly technical meeting of this Society will take place on Tuesday next, the 27th inst., at eight o'clock p.m., at 5a, Pall Mall East.

Photographic Club.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 28th inst., the subject for discussion will be—*The Preparation of Lantern Slides.* This being the last lantern night of the season, members and visitors are invited to bring slides.

A Caution.—The following may be interesting to many photographers:—An order has, it is stated (according to the *Standard*), been issued from the Home Office to "Royal tradesmen" throughout the country, calling upon them to produce the letters patent permitting them to use the designation. The order has caused considerable flutter in Aberdeen, where, by reason of the proximity of Balmoral, there are some thirty tradesmen who, having been appointed to purvey to the Queen's household, use the word "Royal." The letter points out that if the persons are unable to produce letters patent there are certain heavy penalties to which they have subjected themselves for the trading under a false title.——There are many photographers, both in London and the provinces, who are employing the royal arms without any further right than having on one or two occasions photographed members of the royal family.

Improvements in Head-Rests.—Notwithstanding the reduction in the time of exposure that has been effected by the employment of gelatine plates, and the less liability there is to move on the part of the sitter, no photographer who values his reputation will care to forego the all-powerful services of the head-rest, which ever since the application of photography to portraiture has rendered most important aid to the artist in obtaining stability and consequent sharpness. Our attention has been directed to several improvements recently effected in this important studio adjunct by Mr. E. E. Emmerson, engineer, Leeds, who for many years has made this piece of apparatus such a favourite study as to have arrived at as near an approach to perfection in its construction as we ever expect to see accomplished. The characteristics of the latest mechanical efforts of Mr. Emmerson are extreme rigidity combined with great facility of movement and adjustment to the figure. Our readers will remember that we had occasion a few years ago to eulogise very highly the Emmerson head-rest. Since that time the special features to which we then directed attention have been still further improved.

METEOROLOGICAL REPORT.

Observations taken at 406, Strand, by J. H. Steward, Optician,
For Two Weeks ending May 21, 1884.

No. 1256. Vol. XXXI.—MAY 30, 1884.

FREE SILVER AND SENSITIVENESS IN GELATINE EMULSION.

Writing on the subject of Mr. W. K. Burton's method of forming an emulsion by precipitation and subsequent removal of the decomposition products of the operation, we some months ago suggested the possibility which this process seemed to afford of utilising the sensitising action of free nitrate of silver upon the bromide without bringing into force the fogging effect that salt usually induces by its combination with the gelatine.

It is somewhat surprising, considering the important *rôle* that free silver played in rapid collodion emulsions, that something more should not have been done to extend its use to gelatine; but the neglect in this direction has, no doubt, been mainly due to two causes:—First, the deleterious action of the free silver on the gelatine; and, second, the fact that a large excess of soluble bromide in the emulsion, while safe-guarding it from fog, exerts no injurious influence on the sensitiveness of the resulting films if completely removed by washing. In the case of collodion emulsion the result is different; for every fraction of a grain of free bromide employed in the preparation of the emulsion produces an effect upon its final sensitiveness, however thoroughly it may be removed. To secure the highest sensitiveness it is absolutely needful to have an excess of silver nitrate—a condition of things usually adopted in spite of the necessity it brought for increased precautions against fog and the greater delicacy required in all the manipulations. When, therefore, it was found that free bromide exerted no slowing action upon a gelatine film under certain conditions, while it preserved it from fog during preparation, it is scarcely to be wondered that experimentalists should turn away from free silver with its concomitant troubles—far greater in connection with gelatine than with collodion.

It is true that some of the early formulæ for gelatino-bromide provided for, or even attached special importance to, an excess of silver over soluble bromide; but it may be questioned whether the modes of emulsification then adopted really secured an excess of silver, or, in any case, whether films so prepared possessed even the most ordinary keeping qualities. During the earlier days of the gelatino-bromide process the emulsification only extended at the most to a few hours, and the full strength of twenty grains of gelatine to each ounce of emulsion was present during that period. Under such circumstances it is probable that, though according to the equivalents of silver and bromide employed the former might be in excess, yet, in consequence of the shortness of the emulsification and the viscid nature of the vehicle, that complete combination might not have taken place and that both silver and bromide remained in the free or uncombined state. In this latter case the beneficial action of the excess of silver upon the sensitiveness of the emulsion could not arise, though its injurious combination with the gelatine would be proceeding all the time; and though the effect might not be immediately evident, being masked by the action of the uncombined bromide, it remained nevertheless to make itself visible in a very short time after the removal of the soluble bromide.

Thus, Mr. Herbert B. Berkeley, some five years ago, exhibited at one of the meetings of the Parent Society a number of plates prepared in the earlier experimental days of the gelatine process with excess of silver, and which had been kept only a few weeks before they turned red from the action of the silver upon the gelatine. The emulsion was thoroughly washed to free it from the excess of silver, and the plates when freshly made worked perfectly; but, after a short time, the spontaneous decomposition of the gelatino-silver compound set in and ruined the plates completely.

It was a well-known fact that with many of the old and obsolete dry-plate processes very sensitive films (in those days) could be obtained by using a preservative containing a trace of silver nitrate, or (which amounted to the same thing) by not removing the whole of the free silver from the film before applying the preservative. But such plates possessed very poor keeping qualities, and were, moreover, far more prone to fog and other defects than those entirely free from silver. Similarly, it has been proposed on the continent to increase the sensitiveness of our present gelatine plates by treating the dried films with a dilute solution of silver nitrate or other soluble silver salt; but, though the effect sought is in a measure gained, the plates will only keep for a few hours, or, at the most, a few days.

We will revert to collodion emulsion with a view of showing the analogy between gelatine and collodion films in connection with free silver. An emulsion made with a decided excess (not necessarily a large one) of soluble bromide possess considerable keeping powers whether in the unwashed or washed state, but never attains to the highest degree of sensitiveness. Here the soluble silver salt, having a comparatively feeble attraction for the organic matter of the collodion, is monopolised, so to say, by the bromide; no organic compound of a fogging nature is formed, and the excess of soluble bromide acts as a restrainer to any fogging tendency that might arise.

If, however, the conditions be reversed and the silver be in excess we have an emulsion which up to a certain point works well and will attain a sensitiveness greater than in the previous case; after this it commences to become foggy, grows worse and worse, loses its sensitiveness, and finally becomes utterly worthless. If it be used for coating plates, or be precipitated in the form of pellicle just when it has reached the proper stage, the resulting films (or pellicle) retain the good qualities which the emulsion possessed at that stage. This stage—that is to say, the point at which the highest sensitiveness and the least tendency to fog are best combined—may be presumed to arise when exact neutrality has been reached, when the whole of the soluble bromide has been taken up by the silver nitrate. From that moment, though the sensitiveness may go on increasing (by the action of the excess of silver nitrate upon the silver bromide), the injurious action of the free silver exerts itself upon the organic constituents of the emulsion, and, sooner or later, according to the degree of excess, the whole becomes useless.

But let us go a step further. In addition to the excess of silver mentioned in the last instance let us add a certain quantity of nitric acid; the exact amount will depend upon the quantity of silver in excess and other conditions. Now we shall find that when the neutrality point is reached—that is, when the whole of the soluble bromide has been converted—the emulsion goes on increasing in sensitiveness, but retains its good qualities, instead of "going back," as in the previous case. By a suitable adjustment of the quantities of silver and acid an emulsion may be made which possesses the property of keeping, if not indefinitely, at least for a very long period—extending to months at anyrate—and the sensitiveness of which becomes very great.

The first inference to be drawn is that the acid prevents the combination between the silver and the organic matter; but this is, we think, disproved by the progressive alteration in the character of the structure of the collodion as well as of the image produced by the emulsion as the length of action is prolonged. The action appears rather to lie in the power of the acid to prevent the formation of *an insoluble* organic compound. While the free silver goes on producing its accelerating effect upon the silver bromide it is, also, in conjunction with the acid, acting upon the cellulose. In the absence of acid a "pyroxylate" of silver or some similar compound of an insoluble character would be formed which, remaining in the collodion film after washing, produces fog. In the presence of a suitable acid, however, the organic compound, whatever it may be, remains, if not permanently, at any rate for a considerable time, in a soluble condition, and in that state is removed when the films (or pellicle) are washed, and so the fog is eliminated.

Such, at least, is the most plausible theory that suggests itself in explanation of the action of acids in emulsions containing free silver. For instances of an analogous character we need not go beyond the bounds of photographic practice. The addition of acid to the developer for wet plates is simply made for the purpose of arresting or delaying the formation of a precipitate when it comes in contact with a solution of silver. In the case of the iron developer the organic element is absent; but with gallic or pyrogallic acid we have conditions nearly identical with those that prevail in the case of an emulsion containing free silver.

Watch a solution of plain pyro. while a few drops of neutral solution of silver nitrate are stirred in. It instantly becomes black, muddy, and opaque, and in a very short time a dense deposit is formed. Into the same solution of pyro. now stir a little solution of silver acidified with acetic, citric, or, better still, nitric acid, and note the result. At first there is no change; then a slight discolouration, which gradually deepens through various shades of yellow and red until the solution becomes opaque from the intensity of the colouration, but remains clear, and if diluted becomes again clear and transparent. In the presence of acid the formation of the muddy, opaque deposit is delayed for a considerable time, even when the proportion of acid is small; and if nitric acid be employed the time is prolonged to hours.

It is not difficult to conceive that the acid added to an emulsion may perform a strictly similar function; indeed, it is by no means difficult to prove the case if argument by analogy be accepted as proof. But this part of the subject we must leave until next week.

SUBORDINATING OBJECTS WHILE BEING PHOTOGRAPHED.

In the last issue of the American *Photographic Times* we observe that our friend the editor of that well-known journal describes a method by which any one object situated on a different plane from another—and, from its nature and configuration, apt to have its characteristic outline lost by becoming merged into the other—may be dissociated from it so as to preserve its individuality in a photograph. For example: a tree backed by other trees of similar form and colour; a piece of architecture backed by edifices into which its *tout ensemble* becomes merged—such subjects, when photographed, would lose their identity in those situated immediately behind.

The means recommended by our contemporary for discriminating between them is the introduction of an extemporised atmospheric perspective, which would act very much in the same manner as if a huge white screen had been dropped behind the chief features of the view which was being photographed, and allowed to remain there, perhaps, two-thirds of the time of exposure, and then withdrawn. The method by which this "artificial atmosphere" (as it is termed) is obtained is by the igniting of any smoke-producing material between the tree, monument, or whatever other object is to be photographed in its individuality and those objects situated at a greater distance from the camera, but still sufficiently near to mar, by their presence and force, the completeness of the *piece de resistance* of the picture.

Having lately tested the system to which we have referred, we can vouch for its efficacy, especially when the circumstances of the composition lend themselves to this method of obtaining an artificial atmosphere; but in many cases it is not convenient to accomplish, nor, if it were, is it at all times expedient to adopt, such means of improving upon nature. We, therefore, propose here to describe a purely lenticular method by which the same end may in some measure be achieved.

This system is based upon the fact that dissimilarities in the anterior conjugates of a lens of long focus and large aperture exist, and are of so pronounced a character in their bearing upon definition that when an object situated on one plane is made sharp everything else is quite out of focus. The object may be a tree, a garden shrub, a monument in a cemetery, or any other object having a position on a plane removed in a greater or less degree from that upon which are situated the objects at each side of the composition and behind the chief subject here under consideration. Under ordinary circumstances lenses are well diaphragmed down in order that they shall have great penetrative power, or "depth of focus," as it is sometimes designated; but in the case now contemplated an effect of a totally opposite character is sought to be produced. We require to have the individual tree sufficiently sharp to stand out isolated from its forest companions, which must all remain in such complete subordination to it as to form mere accessories to a picture in which it plays the chief part.

Every portrait photographer is well aware that a large portrait combination of (say) ten or twelve inches focus possesses so little ability to represent different planes with an equal degree of sharpness as to render it difficult, when working with full aperture from a near standpoint, to get the nose, eyes, and ears of a sitter delineated with an uniform degree of sharpness; and this discrepancy is still more strongly marked when the focus is longer. We here subjoin a few instances of effects obtained out of doors by working with certain lenses at full aperture.

A tree situated at a distance of fifty feet, having other trees of similar form and colour as its background at a distance of three hundred yards, was projected on the ground glass of the camera by a lens having a diameter of three and three-quarter inches with a focus of thirty inches. When this tree was in sharp focus those at greater distances were represented as a confused mass. For scientific purposes, a correct picture of the tree being required—one in which its individuality would not be interfered with by the intrusion of the details of those behind—this condition of lens and aperture fulfilled the requirement in the most perfect manner. To get the more distant objects delineated with the same sharpness as that of the principal tree a stop of half-an-inch had to be employed, but under these circumstances the outline and individuality of the foliage of such special tree were quite lost.

The position of the camera was now shifted so as to bring within the line of central sight a second tree standing about sixty feet behind the primary one to which reference has been made. When working with full aperture there was a proper degree of distinction between the sharpness of the two, but not sufficiently so to get one tree thoroughly isolated from the other. As this appeared to be a good subject for trying the *Times'* method of effecting a separation of the two by the introduction of the "artificial atmosphere" we inserted a diaphragm sufficiently small to render both equally sharp, in which state their identities became completely merged in each other. A friend who was in attendance to aid in the experiment now ignited some damp hay between the two trees, and the day being calm and well adapted for the experiment a thin film of smoke was soon perceived to spread throughout the space intervening between the trees; the nearer one was shown as being clear and brilliant against a smoky background, in which, however, the second tree was plainly to be seen, but through a hazy medium. At this juncture an exposure was made, and the photographic effect of the intervening "atmosphere" was of even a more pronounced character than that presented to the eye without the camera. The success of the scheme was unmistakable.

A standard rose tree was brought directly against an iron gate having thick vertical bars and an ornamental design at the top, this arrangement having been selected in order to render the subject as confused as possible. The tree was photographed by the full aperture of a whole-plate portrait lens at a distance of eleven feet from the camera, and its outlines were exceedingly well defined. The gate, on the contrary, was so blurred by being out of focus as to be quite indistinguishable as regards its details. From a scientific point of view this photograph possesses interest; pictorially it is offensive. By inserting a diaphragm sufficiently small both gate and tree were brought into an equal degree of sharpness, and a second photograph was taken, in which the gate is so decided in its angular outlines as to destroy the pictorial beauty of the tree. A third one was then taken, and during the exposure a few chips of resinous wood, which had been ignited to an extent sufficient to emit smoke, were laid on the earth between the tree and the gate. On developing the resultant negative it was soon found that an astonishing difference had been effected; for the gate, although sharp as before, was now seen as through a misty veil and subordinate to the tree to an extent greatly exceeding the anticipations of those present during the experiment.

The conclusion at which we have arrived from these and numerous other similar experiments is this—that for such scientific purposes as the delineating of a monument or tree for placing upon wood to be engraved, for isolating it from its surroundings, so as to be made readily amenable to the touching-out brush or for being examined in the interests of science in contradistinction to those of art, a lens of long focus worked with a large aperture fulfils the condition sufficiently well for such purposes. But in all cases where great penetrative range is to be secured by the employment of a small diaphragm, recourse will have to be made to an artificial atmosphere, such as that obtained by the means here mentioned, unless the natural atmosphere be at the time sufficiently dense to effect the isolation, in whole or in part, of the object required to be photographed.

THE NEW COPYRIGHT BILL.

Last week we promised to refer again to the projected Copyright Act, there being one or two points in connection with it, if the Bill pass without amendment, which will prove very inconvenient to many portrait photographers. We allude to those contained in clause 10, which prohibits the exhibition of portraits without the sitters' consent. Some two years back, it may be remembered, we directed attention to this matter, and some discussion on the subject took place in our columns at the time. But the same clause, without alteration, is, we find, included in the Bill now before Parliament.

In this clause nothing is said definitely as to the absolute ownership of a portrait negative taken in the ordinary course of business. By implication, however, it is clearly to be, as it is at present, according to the custom of trade, the property of the photographer Although there is no mention in the Bill to this effect, the clause is very stringent with regard to the use that may be—or, rather, may not be—made of it, thereby implying the ownership in the photograph. It stipulates that in connection with any portrait taken on commission it shall be unlawful for the photographer, whether he owns the copyright therein or not, to sell, offer for sale, or exhibit in public, or in any shop window, "or otherwise," any copy of the portrait, unless he has previously obtained, in writing, the consent of the sitter. This clause will, of course, render it illegal for anyone to exhibit portraits in show-cases or reception-rooms without first obtaining the sitters' permission.

This clause enacts, if it become law without amendment, that anyone infringing it, by making use of the negative without the consent of the sitter (and in writing, too), may be summoned before any court having summary jurisdiction—such as a police court, for instance—when the judge will have the power to order all copies to be given up to the sitter; and not only the prints, but the negative also. Very stringently framed is this clause, for it enacts that, in the event of the copies and negatives not being given up as ordered, or "upon the evidence of one credible witness" that all of them have not been delivered up, the court may grant a warrant to search the photographer's house or any premises belonging to him or that may be suspected of containing them, and, if any be found, to seize them precisely as if they were infringements of a copyright, as in clause 17, which gives power to search premises suspected to contain pirated copies.

The Bill, if it pass, will press heavily on those photographers who, when they happen to obtain an exceptionally-good picture, or the portrait of some well-known or illustrious individual, scruple not to utilise the negative for producing specimens for their show-cases—perhaps, even for sale—whether the sitter acquiesce or not. At the present time if this be done it is, perhaps, questionable if the sitter have a legal remedy, except, perhaps, by process of injunction in chancery, which, to say the least of it, is an expensive and, in this instance, for want of a precedent, a somewhat dubious proceeding. Certainly, at present sitters have not a remedy by summary proceedings, but under the new Bill all they will have to do will be to summon the offending photographer to the nearest police court, when the magistrate will compel him not only to discontinue the exhibition or sale, but to hand over to the complainant sitter all the prints in his possession, as well as the negatives, which will then become his or her property.

We are aware that many show-cases would present a very different appearance to what they do now if it were imperative that portraits should not be exhibited without the sitter's permission first being obtained. In such instances as this the new Copyright Bill, if it become law, will prove very inconvenient. But, after all, we can see no legitimate ground for complaint. If the exhibition of a portrait be not unpleasant to the sitter permission can easily be obtained. If, however, permission be not accorded then the exhibition would certainly be distasteful, and thus cause annoyance.

This same clause will also materially affect the returns of many photographic establishments who do a considerable business in making enlargements without previously obtaining the sitters' permission, simply on the speculation that they may eventually be purchased, or, if not, will serve for specimens. Such pictures, when made, are often purchased, rather to prevent the chance of their being publicly exhibited or disposed of in a manner distasteful to the sitter than because they are actually required; or, in some cases, as we know, even approved of. Under the new Act—if it become an Act—this system of trading will become illegal, and sitters, instead of being compelled to purchase pictures in order to ensure themselves from annoyance, can summon the offending photographer before a magistrate, who will compel him to hand over the enlargement, and not only the enlargement, but the original negative, the enlarged transparency or negative (if any), as well, without payment.

Looking at the matter in an impartial spirit, it will scarcely be disputed that the photographer who has been paid for taking a portrait, in the ordinary course of business, has no moral right whatever to afterwards make use of the negative for his own purpose—whether it be to produce from it copies as specimens for his show-case or reception-room, for sale, or to make an enlargement speculating on its being eventually purchased. He has been paid his price for the work he was commissioned to do, and should, therefore, be content with the transaction.

As the question now stands there appears to be very little chance of this portion of the Bill being amended in favour of the photographer, nor can we see any legitimate ground for amendment in this respect, as it is apparently framed for the purpose of giving protection to the public from the improper use occasionally made of portraits, as well as to secure a copyright in his work to the photographer.

As clause 10 at present is framed, we can, however, foresee one or two legitimate inconveniences that may possibly arise and give occasion for litigation. Although a photographer is prohibited from selling copies of portraits without consent, nothing is said about the negative itself; but it is clear that that is intended to be included as well as the copies from it. If this be the case—and there is no reasonable cause for doubt—how will a photographer have to arrange when disposing of his business? In accordance with the pro posed Bill it would appear that he will have to obtain the consent of each individual sitter before he can dispose of his negatives, which, of course, are part and parcel of the goodwill of a portrait business.

Again: it frequently happens that a photographer may possess a egative, produced in the ordinary course of business, of some one who has, since it was taken, brought himself—or it is suspected he has—within the pale of the law, and copies from it are required to facilitate his apprehension. It is clear that, as the Bill is at present framed, it will be illegal to supply them, even in the furtherence of the ends of justice. However, a short clause may possibly be introduced nto the Bill to meet these and similar slight difficulties, if the matter be brought before the notice of its promoters.

CAN A SILVER PRINT BE PERMANENT?

We return to the subject of the possibility of permanency in silver prints, as opened in our last number. In the course of our remarks we put the question in the following light:—We stated that it was "twofold in its aspect. * * * It is unquestionable that many prints may now be seen toned by the old method of toning and fixing in one operation which, though twenty or thirty years' old, are yet beautiful and apparently unfaded. There are also a large number of photographs still to be found which owe their tone to alkaline toning, and which are equally beautiful and apparently as free from fading as upon the day on which they were first produced." Herein lies the key to the enigma if only it were known how to apply it.

In the first place, it is to be noted that the older toning methods were applied to a great extent to plain paper, while modern toning introduced an era in which albumenised paper was all in all—the delicate beauty of a plain paper print being quite a rarity. Most of the old prints which have remained unchanged are on plain paper. This difference, also, may affect the prints in two ways. Firstly, the solutions made use of will far more readily permeate plain than albumenised paper, and hence permit of a more rapid action of the hypo. upon the silver salts contained in its texture. Secondly, the image instead of being confined to a thin section of the paper, so to speak, as in an albumenised print, is engrained almost into the entire substance of plain paper—facts which have an important bearing upon another consideration shortly to be discussed.

Next, we have the processes themselves to consider, and at once a very striking peculiarity is seen. MM. Davanne and Girard's classical researches upon the cause of fading pointed out the need for using hypo. in much larger quantities for a given number of prints than had ever before been considered necessary, and the full benefit of their recommendation was only felt by those who had adopted alkaline toning—a vast advantage in favour of the latter. Our readers will bear reminding that these experimenters showed that chloride of silver exposed to the action of weak hypo. solution led to the production of an unstable and insoluble silver hyposulphite, which, when contained within the texture of the picture, gradually decomposed and resulted in staining or fading. The recommendation to use a far larger quantity of hypo. than had hitherto been the custom was strongly pressed by ourselves and others, and we believe that in the hands of conscientious workers the plan is and has been generally adopted, thus removing in the main one prominent cause of fading.

Owing to the instability of solution of hypo., especially when containing dissolved chloride of silver, fresh hypo., made daily, was shown to be a necessity where permanent results were desired. In the old method the same bath was used for fixing and toning day after day, week after week, and, in fact, the older it was the richer were the tones it gave. The condition of the relation between the hypo. and the chloride of the image were naturally the same as in alkaline toning, and it is obvious that, in its earlier stages, the "mixed" bath must have been fully equal to the proper fixing of the prints, while after a time it would be both unequal to proper fixing and in that decomposed state which has usually been considered most favourable to fading. Is it not, therefore, a perfectly legitimate suggestion that the unfaded prints which have been left to us from those times have been produced in the earlier period of the bath's existence, when, at anyrate, its fixing powers were not impaired? This would be a very simple way of accounting for the still unfaded prints made by the old process, at least when conjoined to other conditions equally affecting both classes of prints.

Coupled with the use of fresh hypo. (as so prominently recommended in the early days of alkaline toning) was the more complete and thorough washing of the finished prints; and here, again, the new process in a double way had all the advantage in its favour. Prints done by the "alkaline process" have had more chance of surviving on account of that extra washing, and, further, the solution to be removed by such washing would in all probability contain far less of unstable salts, so that, even under imperfect washing, less injurious matter would be left in the one case than in the other. Again the gain is in favour of modern toning.

From this point we are naturally led to consider the question of hypo. in the print. Experiments during the last year or two have, comparatively speaking, been so numerous that the statement can scarcely be doubted that a print may contain large quantities of hypo. and yet remain uninjured after the lapse of one or two years. We think, however, it will be found that prints so experimented upon have been kept dry, and it is a truism to say that many chemical changes require the presence of moisture before they can be initiated; we may instance the well-known fact that in the absence of moisture bleaching in the presence of chlorine does not occur.

We are inclined to believe, however, that the evil due to the presence of hypo. is less the result of the action of the hypo. itself than of the silver salts accompanying it, so that when a finished print is dipped into new hypo. solution and dried without washing there is presumably no unstable silver salt left in the print. On our supposition it should not, therefore, be much acted upon if the print be kept dry—a condition, however, not very likely to occur in the everyday life of a print.

Finally: we have to consider the fading of prints admittedly produced with the observance of every precaution considered desirable to ensure permanence. It is our conviction that in all such cases the fading is due to the action of the atmosphere. We will not now pause to consider whether it is the normal constituents of the air including moisture, or their adventitious accompaniments, the products of combustion, &c. The action arises, and we take the results as seen.

We have, today, opened a packet of old *cartes de visite*, which have been entrusted to us for examination by a photographer whom we know to have been always a most careful worker, and which have been kept wrapped in the same paper in a desk during the greater portion of the period since they were taken (at various times in the year 1866). Some of them are almost as rich as they must have been when first attached to their mounts; others are faded in parts, but not all over. A careful examination, however, soon shows that the fading all starts from the edges; in no one case does the whole of the print show signs of fading. We cannot see any but one conclusion to be drawn from this examination—that the fading has occurred in those portions to which the air has obtained easiest access, namely, the edges, and that when by reason of the pressure of card against card the circulation of air must have been but slight the pictures, carefully made and eighteen years' old, remain in their original state, and, possibly, would do for scores of years longer.

We have found another proof of the same theory. A photographer of our acquaintance keeps a register of all his negatives, a print from each being pasted in a series of books. An examination shows that each of the earliest prints are faded in those parts where air would have the most ready access, but have remained unfaded in other portions. An exception is to be seen at one period embracing a short time only—some of the prints are faded all over. The gentleman in question puts this down to some unknown irregularity in the printing department, as with these exceptions the pictures are uniform for about a dozen years or more.

Now, it is obvious that a plain paper print, with the image penetrating almost the whole substance of the paper, must offer more resistance to the action of the air than the thin film which contains all the image in an albumenised paper print; and so, seeing that in addition the total amount of image-forming silver salt in a plain paper print far exceeds that in an albumenised print, we must, *cæteris paribus*, expect less permanence in the latter.

To sum up our conclusions: we should say the evidence proves that as—at anyrate for a score of years—a silver print kept from atmospheric influences often remains unchanged, a close approach to permanency is a reasonable expectation. As to the relative value of the old and new processes as regards permanency the question is an open one, which will not be solved till further experiments are made; and, as an albumenised paper print possesses a character and a beauty *sui generis*, we think benefit would accrue by a systematic trial and investigation of the old toning system under modern lights.

THEY manage this sort of thing better in "the States," and the hint may possibly be useful to secretaries of scientific societies on this side of the Atlantic. The following announcement is reproduced *verbatim et literatim* from the Chicago *Eye:*—"The secretary of the State of Illinois Photographic Association informs Mr. Ferguson, and *all fools like him*, that no notice of his communications, or others of the same tenor, will be noticed or read to the society." The italics are "the secretary's" own. Happy Mr. Ferguson! To have made such a palpable impression upon the mind of a secretary is more than some people have succeeded in doing; but we rather fancy that, if secretaries on this side adopted the Chicago system of publicly conferring gratuitous characters upon full-aged and able-bodied "Mr. Fergusons," the impressions made would be subsequent rather than anterior to the publication of character, and would be corporeal rather than mental in their application.

"FOR the information of THE BRITISH JOURNAL and others," the same number of the *Eye* gives the following explanation of the pyro. and salicylic acid developer mentioned at one of the meeting by Mr. Edgeworth, and to which we recently alluded in this columns The solutions are composed as follow:—

No. 1.

Pyro.	1 ounce,
Water	60 ounces,
Salicylic acid	10 grains,

which must be dissolved in half-an-ounce of alcohol, as it is very difficult to dissolve in water.

No. 2.

Sulphite of soda—saturated solution.

No. 3.

Lewis' lye—half-an-ounce to 30 ounces of water.

To develope take equal parts of Nos. 2 and 3 and a few drops of a solution of bromide of potassium (twelve grains to the ounce) and mix, and of this solution take in the proportion of one ounce to one of No. 1.

But "Lewis' lye" is an "unknown quantity" here.

APROPOS of the permanency of silver prints, a most interesting example lies before us as we write. It is a very richly-toned print on plain paper—a copy of a chalk drawing—and is so rich and full in colour that it can have altered little, if at all, since the day it was produced; and this, a manuscript note on the back informs us, was in 1856, nearly thirty years ago! It is difficult to believe that, if carefully kept, it will be any different when a century old.

THERE is, however, in connection with this picture another very striking manifestation of a phenomenon which apparently is less known than might be expected—we mean the action of light upon wood. The print is framed in the ordinary way with a plain pine back-board, and upon it is strongly marked in brown a negative reproduction of the print. Our first thought was that some gaseous matter from the decomposition of the image had gradually permeated the print and its mounting, and so acted upon and discoloured the pine wood. A closer inspection, however, quickly showed the cause to be simply the action of light. The print had not been mounted upon cardboard at all, but was simply stretched across the circular cut-out mount, and, being thus kept close to the back-board, the long-continued action of light had printed the image upon the latter in a most decided manner.

WITH a singular effect like this before us it is not difficult to imagine how easily paper made from wood might, when exposed to light, discolour sufficiently to give rise to the imputation of fading when carbon prints were developed upon them.

WE called attention a little while ago to a new patent process for producing bichromates, and from the advertising columns of the *Chemical News* we learn that the soda salt, under Potter and Higgs' patent, is to be had from the manufacturers. They advertise that "it is supplied in large or small lots to suit consumers," though we rather imagine the phrase to allude to manufacturers' rather than photographers' quantities. But the same salt can, doubtless, be purchased in the shops, and there is every probability that it may become an article of constant use on account of the advantages it possesses. It is very soluble in water, which will take up its own weight, and it is lower in price.

M. LÉON VIDAL writes to *La Nature* to expose the perpetual photographs-in-natural-colours craze, which has of late again seized hold of the public. There has recently been quite a noise, he says, about a pretended new invention destined to revolutionise the photographing of colours, and he deems the moment opportune for explaining how the feat may at anyrate in one way be performed. A weak print is made from a negative, and after finishing is well washed. This print is then tinted by flat washes of the colours desired, which are diluted with salted albumen instead of water. The print so treated is next floated on a sixty-grain bath, dried, and placed under the negative, care being taken to ensure its proper registration. The rest of the operations are as usual. Another method consists in painting a weak proof with water-colour pigments let down with salted albumen. It is then coagulated with alcohol, recoated with salted albumen, floated on silver, printed, and finished as usual as just described.

BLACK surfaces can also be so treated, according to M. Vidal, so as to obtain a print more in accordance with the old and faded original when a dark oil painting has been copied. There is nothing new in all this, he says, and he only describes it so as to put people on their guard from accepting as a miracle what is nothing but a *tour de force*—ingenious, doubtless, but of no value, artistically or scientifically.

THE days of iodide of cadmium for collodion purposes have passed their perihelion, we should imagine, though large quantities of collodion are still being made; but we hear of a new use for the metal—a well-known firm of nickel refiners, Messrs. Henry Wiggin and Co., of Birmingham, having invented a new metallic alloy of cadmium, which they have registered under the name of "silveroid." It is said to be of great whiteness, brilliancy, and tensile strength, and producible at comparatively small cost.

THE beautiful coloured afterglows have still another explanation. Signor Aloise G. Moceingo describes them as extra-telluric, interplanetary, or cosmic conditions recurring at long intervals, possibly never before having arisen since man's advent upon earth!

OUR readers may possibly remember the life album designed by Mr. Francis Galton, of photographic-average fame—a book in which was to be placed the life history of the owner, with details about his grandfather and grandmother, with their progenitors for some number of "great, great, greats." A valuable prize was to be awarded to the compiler of the best series of records, which were to include photographs at various ages. Mr. Galton writes that he has received upwards of one hundred and fifty good records of different families.

WE learn that platinum has been found in New Zealand in a quartz vein—a most unusual occurrence. We do not, however, think it at all probable that the "find" is likely to lessen the value of this refractory metal, nor, as a consequence, reduce the cost of platinotype printing.

THE total number of applications for tickets for the British Association this year is 772, and the Council have resolved not to receive any more prior to the meeting at Montreal, when members and associates will be elected as usual.

A NEW use for collodion is found as a fixative for microscopic sections. The method of using it is to mix the collodion with oil of cloves (one to three) and paint the microscopic slide with it by means of a fine brush at the time of using. Then the sections are placed upon the slide when painted, and the oil driven off by heat. Guy recommends the collodion and oil to be applied separately, the microscopic slides to be coated just like the collodionising a plate, and kept in stock. When required for use they are moistened with the oil of cloves, which is afterwards driven off by heat.

HARDWICH ON LIME-LIGHT EXPLOSIONS AND THEIR PREVENTION.

In the following experiments with flame extinguishers, or "safety tubes" as they are sometimes termed, the tubes were attached to the taps of the lantern jet when the contrary is not specified. The explosive ethoxo gas was forced through them by means of small india-rubber balloons, and was burnt at the orifice of the jet. To make the article complete the experiments should have been repeated with *oxyhydrogen* gas, but I am not sufficiently at leisure at the present time to be able to do this.

No. 1. A Hemming's safety tube, half-an-inch long by half-an-inch wide, made with 360 of Kirby's S.W. pins packed in tightly side by side. The pressure of gas reduced about thirty per cent. The flame passes through the tube and shatters the balloon on the other side.

No. 2*a*. A piece of cane one inch long. Pressure reduced thirty per cent. Result: same as No. 1, balloon being blown to pieces.

No. 2*b*. Pieces cut out from the centre and best part of the cane carefully fitted into a tube three-quarters of an inch long and three-quarters of an inch wide. Pressure reduced about twenty per cent. Result: same as No. 2*a*.

No. 3. A column of fine shot (sold as "dust shot") two and a-half inches long, and reducing pressure of gas about thirty per cent. Flame passes readily, as in No. 1 and No. 2

No. 4. A Broughton safety chamber consisting of a tube $\frac{7}{13}$ths of an inch long and $\frac{3}{8}$ths of an inch internal diameter, filled with granulated pumice, previously screened by means of two sieves, the top sieve containing forty-eight meshes to the inch and the bottom sixty meshes. This tube reduces the pressure of the gas about twenty per cent. The flame does not pass it, and the balloon on the other side remains intact.

No. 5. Same as No. 4, but the pumice chamber is separated from the jet by a piece of stout vulcanised tubing eighteen inches long and a-quarter of an inch internal diameter, in order to increase the volume of explosive gas. The flame now passes through the pumice with a loud report and bursts the balloon.

No. 6. Same as No. 4, but with a Chadwick back-pressure valve attached to the pumice chamber on the balloon side. Flame passes through and destroys both valve and balloon.

No. 7. Same as No. 6, but with the valve on the *jet* side of the pumice chamber. Flame passes through the combination exactly as before.

No. 8. A Broughton safety chamber, $\frac{7}{13}$ths by $\frac{3}{8}$ths, emptied of its pumice and filled with filings of "soft solder" (two parts of tin to one part of lead), sifted by means of two sieves—one containing thirty-six and the other seventy meshes to the inch. Pressure of gas reduced about twenty per cent. Flame arrested, and balloon intact.

No. 9. Same as No. 8, but eighteen inches of quarter-inch tubing between the jet and the safety chamber. Explosion more violent than before, and balloon jerked upwards into the air, but not injured.

No. 10. Same as No. 8, but chamber filled with sifted scrapings of slate pencil instead of filings of soft solder. Pressure of gas reduced about twenty per cent. Result as in No. 8. Flame intercepted and balloon saved.

No. 11. Same as No. 10, but eighteen inches of quarter-inch tubing between the jet and the safety chamber. Result as in No. 9, balloon being thrown upwards into the air but not broken.

No. 12. A Broughton safety pumice chamber, same as No. 4, but larger, being three-quarters of an inch deep and three-quarters of an inch wide, not attached to tap of jet, but separated from it by a tube eighteen inches long and quarter-inch internal diameter. Pressure of gas reduced about twenty-five per cent. Result satisfactory, flame being intercepted and balloon saved.

No. 13. A tube three-quarters of an inch deep and half-an-inch wide, filled with zinc filings, and screened as before. Pressure of gas reduced about twenty-five per cent. Flame arrested as in No. 12. In this experiment I examined the gas remaining in the balloon, and found it strongly acid and contaminated with the products of combustion, which appear to pass through the tube, although the flame is extinguished.

In tabulating the results of the above experiments the first thing which strikes me is that the safety tubes in which the channels for passage of gas were *straight*, so that you could see the light shining through on holding them up to the light, all failed; whereas the tubes which had zigzag passages, as originally proposed by Mr. Broughton, of Manchester, succeeded (with the exception of the shot, which was evidently too coarse). The pumice, however, seemed to require a longer column than the others, and this I did not at first understand. On opening the Broughton chambers, however, the reason was obvious, for they had been a long time in use, and the granules had sunk down, leaving a portion of the upper part of the tube empty.

Metal filings (of which, perhaps, filings of pure *tin* would be the best) have this advantage—that they are better conductors of heat, and must, therefore, tend to cool the flame. They are also not liable to disintegration and dust; on the other hand, the chlorine contained in the oxygen gas would be more likely to affect a metal than to act on a substance like slate or pumice.

The screening of these granules is a very simple operation. All that you have to do is to cut two squares of wire gauze of the right degree of fineness, and then to lay the filings on the top piece and tap it gently with the handle of a knife. All that passes through the first sieve and remains *in situ* on the second should be retained for use. The fine dust will pass the second sieve, and must be rejected.

Flame extinguishers should be carefully made, and should also be examined from time to time to see that they are quite full. Sift out the whole of the fine dust from the pumice, or it will be blown through into the flame, causing it to flicker. Fill the chamber to the top, tapping it gently until the pumice has well settled down; then remove the excess with a straight edge, and keep it in position by a circle of wire gauze seventy meshes to the inch. The tube should be made to open easily, with the top nozzle screwing upon a leather washer to make it air-tight.

As regards the proper position for the safety tubes: I suggested, in my paper read before the Edinburgh Photographic Society, that they should be placed on the nozzles of the ether tank. I now see, however, that this would be too low down, and that the volume of the exploding gas in front would be dangerously large. The nozzles of the dissolver would be better, but the taps of the jet would be best of all, unless the jet could be made purposely with a safety tube between the mixing chamber and the nipple, which is *theoretically* the right place for it to occupy.

Taking into account the number of experiments I have made, and the repetitions of the same in cases where any doubt remained, I think I am in a position to say that a safety chamber three-quarters of an inch long and half-an-inch wide on each tap of the jet will give complete security. Some, however, have thought that a back-pressure valve should be added to prevent *suction* when a weight falls off from the bag. This at first was my own opinion, but I now see that I was mistaken, and that the falling of a weight does not produce that strong suction which is usually supposed. When there are *two* bags no doubt the gas passes rapidly from the one to the other in such a case, but that is explained by the loaded bag *forcing* it into the bag from which the weight has fallen. With a single bag, as in the ethoxo process, the compressed gas expands and regains its original bulk, but it has no power to draw in either fresh gas or liquid. To prove this you have only to take an empty wash bottle and connect it on one side with a bottle of the same kind containing water, and on the other with a loaded bag of air. Now, remove the weights suddenly, and you will see that the level of the water is not disturbed, and that the empty bottle remains dry. If there had been suction to an appreciable extent some of the water would have been drawn from the one bottle into the other.

So satisfied was I with the result of this and a few similar experiments that I did not hesitate to fill a pig's bladder with explosive gas and to pull the forty-pound weight off it whilst it was blowing a strong, hissing flame at the orifice of the jet. The flame passed back into the jet with a report, but it stopped at the pumice chamber and did not enter the bladder. I tried the same experiment a second time with the same result; there was either no suction at all or not enough to interfere with the protective power of the safety tube.

Back-pressure valves, however, although not so urgently needed in the ethoxo lime light, are most useful in the oxyhydrogen process when two bags are employed with separate boards and weights; and it is not easy to see how an explosion could happen in such a case, even without safety tubes. The two together—tubes and valves—would give absolute security, but the pressure of gas would be much reduced, and heavier weights would be required.

I have been in correspondence lately with the North British Rubber Company, of Charlotte-street, Manchester, and they have sent me a sample of vulcanised sheeting, $\frac{1}{16}$th inch in thickness, which I find to answer admirably for Chadwick's back-pressure valves. They have also recommended the "pure grey rubber" tubing, as less liable to tear or crack than the red or any other variety. T. Frederick Hardwich.

COLOURED AND NON-ACTINIC LIGHT.

It is a pleasure to find the pen of so able a writer as Mr. Lewis Wright engaged, as it was in your issue of the 16th instant, in the consideration of this subject; and I should not have felt disposed to comment upon that gentleman's remarks if it were not that, as it appears to me, he has somewhat overlooked an essential factor in the question, which I believe only requires to be pointed out to be admitted.

Mr. Wright says that we must proceed by "finding the *least* actinic bands in the actual spectrum on the actual plates to be used, and by finding, with the prism, coloured glasses or other media which correspond with these bands. Any other method is a kind of 'hit or miss' that is sometimes necessary, but which, when better methods are accessible, is like groping in the dark."

The method recommended by Mr. Wright is certainly that which has been adopted and advised pretty generally; but there are several reasons why the result thus arrived at may not be the true one. The first and principal objection to it is that it takes no account of the different *illuminating* powers of the different parts of the spectrum. Suppose it to be found that the lower down the spectrum the less is the photographic action, it would follow as a matter of course that deep crimson red or magenta is the proper colour to use in the laboratory. As a fact, however, the red possesses very much less illuminating power than the yellow, yellow-green, and yellow-orange; and the question should rather be—Which part of the spectrum possesses the least effect upon the photographic film in proportion to its illuminating power? Now, although various portions of the actual spectrum *could* be actually isolated and their luminosity compared, I am not aware of its ever having been done in this connection. Moreover, the nature of the source of light would so greatly affect the luminosity of the various portions of the spectrum produced from each particular radiant, that a number of tables would have to be made.

Another reason why visual comparison through a spectroscope might fail to indicate the safest medium to use is that the ultra-violet rays which have such a powerful photographic effect would escape notice altogether.

Yet, again: of the media which are available there are none that permit the passage of light from one portion of the spectrum only, and to have to calculate the effect of small and constantly-diminishing quantities of photographic effect would render the problem extremely difficult, and probably cause the answer to come out incorrectly. Further: there appears to be great difficulty in obtaining definite results with spectrum photography. The observations of the same experimenter made one day may not accord with those produced upon another occasion, and great differences occur in the statements of different experimenters.

Captain Abney states that the effect of the addition of iodide to a bromide emulsion is to make it so much less sensitive to the orange that plates containing iodide, as plates now made generally do, may be safely manipulated in an orange light; whilst pure bromide ones are sensitive as low down as the orange, and require to be worked in a red light. Dr. Eder has quite recently stated that the addition of iodide renders plates *more* sensitive to the yellow, which is close to the orange; and his statement, therefore, may be taken as opposed to that of Captain Abney and more in accordance with the later experiments of Sir J. Herschel, who considered the addition of iodide necessary in order to obtain sensitiveness in the lower portion of the spectrum. In any case the actual difference is much less than the photographer, reading of the results of experiments in spectrum photography, would be apt to believe.

In photographing a sheet of bright-coloured ribbons with rapid emulsions of three varieties—one containing only bromide, one with five per cent. of iodide, and one with ten per cent.—the difference of sensitiveness to the different colours was so slight that it could not be absolutely affirmed. If there were any difference I incline to think that the result was slightly in favour of Sir J. Herschel's and Dr. Eder's views—that the sensitiveness with the iodide added was a little greater in the orange than with the pure bromide; but the amount of difference was so small that, as I have said, I should not like to affirm it as a fact.

I think it must be admitted that a simple and better manner of ascertaining the comparative safety of any two is to find some distance at which a certain visual power exists—by reading, for example—and then to expose a plate for a certain time at that same distance.

Mr. Wright, in speaking of the necessity for ascertaining the least actinic bands in the actual spectrum on the actual plates to be used, doubtless assumes, as anyone would do from what has been written on the subject of spectrum photography, that slight differences in the composition of the plates—such, for instance, as that which has been referred to, namely, the addition of a small quantity of iodide—will cause considerable difference in comparative sensitiveness to different parts of the spectrum, and that this will correspond with a proportionate difference in the behaviour of the sensitive compound to the coloured light given off by natural objects or passing through tinted screens. That this is not the case I believe I have shown.

There is another point upon which Mr. Wright appears to have been misinformed. He says:—"It appears well established that some *small* amount of exposure in preparation is actually essential to sensitiveness itself." I suppose the ground for this is the fact first demonstrated by Mr. W. K. Burton, that preliminary exposure does make a film more sensitive to faint traces of light, as shown in the higher figures of the sensitometer; but any apparent sensitiveness thus gained is of very doubtful utility in the camera, and, certainly, it cannot be stated as a general fact that light in preparation is essential to sensitiveness. That would imply that there is no sensitiveness without it.

Mr. Wright suggests glazing a lantern with strips of differently-coloured glass, so as to produce a composite white light. I showed a lantern on a similar principle at the meeting of the Photographic Society of Great Britain on the 13th inst. In this lantern the light from two paraffine lamps—one glazed with "stained-red" glass and the other with a yellowish green—was projected upon a white card and then passed through tissue paper. The light given, compared with daylight, was somewhat yellowish; but not so yellow as when the coloured glasses were removed and the lamp turned down to give about the same luminous effect to the eye. Nevertheless, whilst with the latter arrangement—low lamplight reflected from card and passed through paper—a strong image was given upon a plate held for a minute's time at a reading distance. From the composite white light the image was so faint that it could scarcely be said to be visible at all, and would not have shown as fog if there had not been a sharp edge to the mask covering the remainder of the plate.

No one need expose a plate to the light that he is working so much as to be equal to being held full square to that light for the space of a minute at a reading distance; and, therefore, with ordinary precautions, such a light may be safely used for developing purposes, although not so absolutely safe as a yellow light.

There is a point in my experiments upon which an explanation from such a lucid and careful writer as Mr. Wright would, I think, be welcomed. The stain in the glass known as "stained-red" is one which, when in a thin layer, is yellow, and is due to silver. By increasing the thickness of the layer the colour to the eye passes first from yellow to orange, then red, and lastly ruby or crimson. A gold stain, when thin, appears pink or pale purple red; but upon increasing the thickness of the layer the colour appears to incline less and less to the magenta, and finally tends more to the orange-red than the piled-up silver-yellow. The ordinary ruby glass stained with copper undergoes no such changes. W. E. Debenham.

PHOTOGRAPHIC INDUSTRIES.

THE LANTERN FACTORY OF MESSRS. W. H. OAKLEY & CO.

However correctly it may be asserted of certain retail tradesmen that they display their entire stock in their shop windows, such cannot, at anyrate, be said of Messrs. W. H. Oakley and Co., who do not put themselves to the trouble of displaying any of their lantern or philosophical appliances either in their window or, for that matter, in their shop. In good truth it must be said that the outside of the premises in Grange-road, Bermondsey, affords not the slightest clue as to their being connected either directly or indirectly with the philosophical, not to say fine, arts. For this there is a good reason as will soon be perceived.

Established about forty years since as an operative engineers' factory, it is only of comparatively recent date that a photographic and lantern branch has been grafted on the original engineering business; but this department has already grown into large proportions, more especially that devoted to lanterns and lantern appliances, and to which we purpose confining our notice on the present occasion.

The more purely engineering department of this establishment is situated on the ground floor—a fact of which the visitor becomes immediately aware as soon as he passes the threshold, the shelves on his right groaning under iron pipes intended for gas or water purposes, those on the left with numerous and varied appliances cognate to mechanical engineering, while straight ahead and in the distance appear turning lathes, work benches, and the paraphernalia of a large workshop, which are propelled by two steam engines of six- and ten-horse power respectively. According to the pressure of orders these are worked either singly or conjointly. With this portion of the establishment, however, we have nothing to do at present, but proceed into an upper room crammed to repletion with what we may designate lantern stock in every stage of progress, from the separate pieces which comprise the elements of an outfit to the completed lantern outfit itself.

When, twelve years ago, the determination was arrived at by this firm to enter into the lantern business, the intention was formed to keep as much as possible out of the well-worn and beaten paths in which such a branch of business had previously been conducted; and in adopting lantern making as a speciality, Messrs. Oakley and Co. resolved to apply their powerful mechanical appliances and resources to this end, and to manufacture everything except lenses and slides, thus taking a new departure in their business as far as such was possible. This, it will be remembered, was soon after the period when the lantern had slowly emerged from its quondam position as a toy into the *rôle* of a scientific instrument, and when there was a tolerably wide field before any ingenious and enterprising aspirant who chose to enter into that business.

Among some appliances possessing a degree of interest more or less historical, we were shown the original slide adapter from which arose, or sprang, others of the adapting class; that is, those by means of which slides of various dimensions can be brought into a central position in the axis of the condensers. The notched adapters (if such a term be admissible), now well known from the publication of their structural details in THE BRITISH JOURNAL OF PHOTOGRAPHY and elsewhere, seem to owe their inception to the unpretending slide submitted to our inspection.

Knowing the importance of system when exhibiting lantern slides, we were interested in a box cheap and of somewhat unassuming appearance which was presented to our notice. It bears the not very poetical name of a "consecutive box," and we think a brief description may be useful to some who, like ourselves, have never before become acquainted with this useful piece of apparatus. It consists of a box in which the slides are laid in proper consecutive order. It has a bottom and sides, but no top—at anyrate while in use. The sides, however, are formed of corner pieces so arranged as to render it quite easy to pick out one slide after another for transference to the lantern. The simplicity of this is almost ludicrous—the value unmistakable; and after this we shall not willingly be without a "consecutive box" when exhibiting photographs by the lantern.

Another appliance with which we were much pleased was a portable screen elevator. This piece of apparatus is not only quite portable, but can be adapted to the dimensions of any screen which the exhibitor thinks it prudent to adopt—anything, for example, from five feet square to twenty feet square, beyond which it is not considered necessary to go in the usual course of such exhibitions. We do not intend to describe this apparatus here, but content ourselves with saying that by an ingenious and very simple adaptation of rods, which fix into each other by something similar to fishing-rod joints, the dimensions of the supporting frame may be adjusted to suit any particular size of screen adopted under any special circumstances.

We were much pleased, also, to see a simple method by which the tap of a gas-bag could be so locked up as to be placed beyond the tampering propensities of any curious or prying spectator. Those who have had experience in lantern work know the feeling of insecurity engendered when leaving an oxygen or hydrogen bag fully charged under the control of inexperienced or ignorant persons, who, without intending any harm, might amuse themselves by turning the taps in order to hear the gas rush out. In the protected tap immunity from such a course is secured by a metallic belt being passed round it, so as to prevent the tap being turned round or tampered with, a small padlock securing it when in position.

We could perceive that Messrs. Oakley and Co. did not look with much complaisance upon the supply of oxygen from metallic chambers in which the gas was compressed as when gas bags formed the reservoir. The objection seemed to lie in the constant changing and diminution of the pressure, which rendered it necessary to have a continuous supervision of the tap, whereas with the bag this is unnecessary. The initial pressure in the gas tank is about 550 pounds, and from this down to the minimum the transition is very sudden. In the case of steam pressure, on the contrary, it can be reduced from fifty pounds to ten pounds with ease; not so, however, is this the case with an initial pressure so great as that in an oxygen cylinder.

The difficulty of getting a camera erected on a rail fence from which to photograph a race-course, or on the gunwale of a vessel, will be readily appreciated. We were shown an appliance specially adapted to meet such a case, and it was most effective.

As might well be understood, the preparation of oval or circular *shapes* in metal for cutting out mats for lantern mounts is, in a large factory such as that here under notice, a matter involving no trouble or difficulty. Accordingly, we saw many such shapes just as they were brought from off the oval chuck of the turning-lathe.

The machines for shearing and bending iron plates into lantern form, and also for punching into them the apertures appropriate to the various requirements of the business might here be referred to, but could not so easily be described.

Our readers would probably feel but small interest were we to attempt a description of the various operations connected with the woodwork of this lantern factory, which were carried on in an adjoining room; but the machines for grooving the wood for boxes and frames are of the most perfect order, and evince great ingenuity.

One of the most useful devices manufactured by this firm consists of a reading-lamp and desk. These are erected upon a slender pillar, the lower end of which screws into the floor. The height can be adjusted to suit the requirements of the lecturer, and the light emitted from the lantern is confined to the MS. of the lecture lying on the desk. A touch of a tiny bell, or the flashing of a signal, announces to the exhibitor the proper moment at which to change the scene.

Noticing the excellent quality of the india-rubber goods employed by this firm, we were informed that one of the family was connected with a large india-rubber factory, by which they were enabled to have just the class of goods made for them which they required.

In the stock-room drawer after drawer was pulled out, displaying a plethora of appliances for lantern manufacture, the season for which will soon commence; for in this trade the shadow of winter is cast long before the advent of that season.

In conclusion: we were much pleased with all we saw at this extensive establishment, and felt impressed with the fact that there was no fear of this country losing its *prestige* in lantern manufacturing so long as able mechanicians and philosophic instrument-makers like Messrs. W. H. Oakley and Co. are to be found engaged in the production of apparatus which are in modern life now found to be indispensable.

ON THE SENSITIVE-TO-COLOUR COLLODION PROCESS, OR THE CORRECT REPRESENTATION OF COLOURS BY BLACK PHOTOGRAPHS.*

I.—INTRODUCTION.

MENTION has already been made in these pages of the fact that I have succeeded, according to the principles laid down eleven years ago, in preparing collodion plates which are at least eight times as sensitive to the yellow as to the blue of the spectrum, and that it has, therefore, been possible to photograph the colour scale in my *Lehrbuch*, so as to give the blue, yellow, and green their proper values. The matter has excited the liveliest interest in scientific and photographic circles, and stress is everywhere laid upon its importance in reproduction by photography. Consequently, the Association for the Cultivation of Photography has resolved to acquire the process, and by its publication to make it public property.

According to the decision of the Association I herewith publish the process, and begin with the purely practical part, referring to articles in former years, and to that just published [see page 327], for the principles of the matter. Later on I shall give a more minute description of my experiments.

Ordinary portrait collodion shows its highest sensibility to the dark-blue parts of the spectrum, which are erroneously called "indigo blue." It is only after a very long exposure that a sensitiveness to green, yellow, and red appears. According to the principle first demonstrated by me, one can increase the sensitiveness to green, yellow, and red by the addition of dyes which absorb these rays.

* This is the process "crowned" by the Berlin Association for the Cultivation of Photography.

[There still prevails in many circles, even in those where one would expect better things, the most complete ignorance respecting the effect of these additions. For example: one could lately read in a trade journal that "the employment of cosine does not produce the slightest increase of sensitiveness to yellow." How far this contention flies in the face of facts will best be seen from this—that the collodion to be hereafter described already gives a representation of the yellow of the spectrum after an exposure of one second, while the same collodion *without* cosine shows but a slight trace of the action of yellow after an exposure of one minute. The sensitiveness to yellow is at least increased sixtyfold by the measured addition of eosine to that collodion. But should it be objected that that applies only to the spectral colour, and not to the ordinary pigment colours, one can easily convince himself that the sensitiveness to yellow pigments is also greatly increased by the addition of eosine. For example: one may photograph a colour-scale through yellow glass upon pure bromised collodion and upon collodion stained with eosine, and will at once recognise the increased sensitiveness of the latter to yellow. That by the addition of many dyes the sensitiveness to blue rays may also be decreased I have already mentioned in the third edition of my *Lehrbuch*, page 153. Wet eosine-stained bromide of silver plates are about two and a-half times less sensitive to blue than unstained bromide of silver plates. Any reader who may be interested in this point is referred to what I did in 1878, and to the chapter treating of that subject, pages 149 to 159 of my *Lehrbuch*.]

The great majority of these dyes act best upon collodion dry plates, as proportionately few are suited to the wet process. To these belong the dyes known under the name of "eosines." In commerce two kinds of eosine are known—eosine yellow (the scientific name, fluoro-tetra-bromide of potassium) and eosine blue (the scientific name, fluoro-tetra-iodide of potassium); besides methylated, chlorated, and nitrated products—all of which I have tried. Keeping back the details of the action of these for the present, I only remark here that these substances are produced as important dyes, but that they are not to be had pure commercially, and are often adulterated with dextrine, &c. These impurities have an injurious effect upon the silver bath.

The Joint Stock Analine Dye Manufacturing Company, near the Silesian Gate (Berlin, S.O.), has, at my request, undertaken to prepare purified dyes for photographic purposes. Of the two eosines—yellow stick and blue stick—the latter gives rather more intensity than the former. When united to alkalies both show a so-called fluorescence (shimmer—changing of colours like shot silk); in dilute solutions they dissolve with ease in water, but not so readily in alcohol, and they absorb very greedily the yellow-green and blue-green rays. When added in proper proportions to collodion dry plates they render them sensitive to these rays, and upon this their action in the matter of sensitiveness to colour is based. Beside these substances, a dye (not yet exactly determined—cyanosine), which I owe to Dr. Martius, has proved a very active sensitiser of wet plates for yellow rays. It indeed surpasses the eosine, since its absorption region extends further towards the red of the spectrum, and, consequently, it not only gives rise to a sensitiveness to yellowish-green, as eosine does, but also to a sensitiveness to orange.

Unfortunately, this material, as sent into the market, is not pure enough for photographic use, and as yet the Aniline Dye Manufacturing Company only make a special preparation for photographic use of the yellow-stick eosine, which, by my directions, they re-crystallise twice. This I recommend provisionally to all who may desire to experiment with stained collodion. Afterwards, erythrosine is to be specially prepared for photographic purposes, and then, of course, it will be preferable to the eosine. If this dye be tried upon gelatine or collodion dry plates, one will soon see that the former plates can be rendered by it, at most, twice as sensitive to the yellow of the spectrum as to the blue of the spectrum. This would practically be of little advantage, since the yellow of pigments is so dark compared to the yellow of the spectrum that, as I have already mentioned, the sensitiveness to yellow must exceed the sensitiveness to blue by twenty-five times in order to its representing the pigment yellow as really lighter than the blue. Collodion plates furnish much better results. At the very first attempt I succeeded in preparing plates which were from eight to ten times as sensitive to yellow as to blue. I am, therefore, quite justified in turning for the solution of this interesting problem direct to the collodion process.*

The action of the dyes, however, depends greatly, as I have shown both above and on former occasions, upon the composition of the collodion. If about five per cent, of a 1:400 solution of eosine or cyanosine be added to some ordinary iodised collodion, one will observe but little sensitiveness to yellow on taking an ordinary photograph. I, therefore, made experiments with iodised collodion containing various proportions of bromide, and these showed that the *sensitiveness to yellow increased the more the richer the collodion was in salts of bromine.* This experiment at once pointed to the use of a *bromised collodion.* It proved, however, that a slight proportion of iodine had a favourable effect upon the general sensitiveness. If the silver bath, by long continued use, already contains iodine, then a sufficient quantity of iodide of silver will be precipitated by it upon the plate, so that pure bromised collodion can be used; but when the silver bath is freshly prepared and poor in iodine it is as well to add five per cent. of pure iodised collodion. Generally, it may be assumed that the sensitiveness to white light of the bromised collodion plates stained with eosine and sensitised in a bath containing iodide of silver is three times less than the sensitiveness of ordinary portrait collodion.

II.—Formulæ.

Solutions of Dyes.—For the present—that is, so long as other sufficiently-pure dyes do not find their way into the market—eosine-blue and eosine-yellow are recommended. Dissolve half-a-gramme, by prolonged agitation, in 160 c.c. of alcohol of 95°. Let what remains undissolved settle down, and then pour off the clear liquid.

Collodion.—Dissolve two grammes of bromide of cadmium in thirty c.c. of alcohol; filter, and mix one volume of the filtrate with three volumes of neutral celloidin collodion containing two per cent. of cotton. For many purposes a thicker film is preferable. Such may be obtained by dissolving two and a-half grammes of bromide of cadmium in thirty c.c. of alcohol, filtering, and mixing in the above proportions with a two and a-half (instead of a two) per cent. collodion. Such a collodion flows with difficulty and silvers more slowly. To ninety-five c.c. of the above collodion add five c.c. of the above eosine solution and shake well. The collodion is best kept in yellow bottles and exposed as little as possible to daylight. (An increase of the proportion of the eosine solution does not increase the sensitiveness to yellow. It only lessens the general sensitiveness of the plate; but lessening the proportion of eosine does lessen the sensitiveness to yellow. The above proportions were arrived at by numerous experiments with mixtures of various proportions.)

The Silver Bath.—Crystallised silver salt 50 grammes, water 500 c.c., 1:100 solution of iodide of potassium 13 c.c., acetic acid until a distinctly acid reaction is observable (at most six drops). Nitric acid does not recommend itself for sensitising, as it acts too strongly upon the dyestuff. It must be expressly mentioned that eosine destroyed by acid will be converted into a yellow dye which no longer exercises the desired reaction of increasing the sensitiveness to yellow, and, therefore, an excess of acid is to be avoided. Keeping in view the danger of the silver bath being contaminated by the impurities which are added to the existing commercial dyes, I do not consider it advisable to silver the stained collodion plates in the same bath in which portrait plates or other plates for reproductions are to be silvered; therefore, in order not to use too much bath solution I use a flat bath and not a dipping bath.

Developer, Intensifier, and Fixage.—For these the usual solutions used in the ordinary wet process may be used. The plates are treated just as in the wet process. It is one of the advantages of this process that it does not necessarily entail any change in these operations, and that anyone acquainted with the wet process can at once work with stained collodion. The pyro., corrosive sublimate, uranium, and lead intensifiers can all be used just as upon ordinary collodion.

III.—Mode of Working.

It is best to gelatinise the plates. Dissolve one gramme of gelatine in 300 grammes of warm water, filter, and when cold add to it 6 c.c. of a 1:50 solution of chrome alum, prepared cold. (Clean the plates with acid, wash them, lay them on a flat dish amongst distilled water, and then coat them twice with the gelatine solution. The first coat only serves to drive off the water, and what runs off should not be collected. This operation is best performed in a room that is not too cold.) Coat with collodion as usual, but silver a much longer time, as the bromide of silver forms very slowly, taking at least five minutes. The stronger the silver bath the more rapidly does the formation of silver take place. *The bath should be tested with litmus for acid and the requisite acetic acid added before beginning work.* With regard to the lighting of the dark room one does not need to be too anxious. I recommend a lamp with an orange-coloured lamp chimney. Eosine itself renders the collodion but little sensitive to light. If the plate be held as much as possible in the shade, even yellow light may be used for the dark room. When I have to work with the bare yellow light I hold the plate so that it is canted away from the light, and thus there is no danger to be dreaded.

Exposure.—As already mentioned, the sensitiveness of the eosine-stained bromide plates is about a third of that of ordinary iodised collodion plates. From that the length of the exposure can be measured. In taking coloured pictures, such as the colour scale in my *Lehrbuch*, the increased sensitiveness to yellow does not appear so strikingly as many might expect. But on the other hand it does come out very distinctly in the case of rose-coloured dyes, as the madder lake of the colour scale. These stand out with their proper values. But for other tones (as green) the action of the eosine also appears very positively. If it be desired to still further diminish the action of blue, recourse must be had to *yellow glass slides.* The accompanying* scale was photographed through a yellow slide. In the choice of these

* My experiments with gelatine plates will be described afterwards. I shall only remark here that even the Parisian isochromatic plates of Mr. Clayton and M. Tailfer were only twice as sensitive to yellow as to blue.

* This allusion is to the illustration which accompanied the article in the *Mittheilungen.*

some care must be exercised. A slight want of sharpness is observable in this photograph, the cause of which is that the only piece of yellow glass at my disposal was not plate-glass, but foggy, yellow window glass. Through plate-glass one would get faultlessly sharp pictures. It is also very important to get the right shade of yellow in plate-glass. If it be too dark it prolongs the exposure too much; if too light it does not sufficiently counteract the blue. I distinguish the proper shade by the use of the spectroscope. To be able to use a spectroscope will soon be a matter of necessity for those who wish to take up such experiments; but he who cannot use the spectroscope may test for the tint photographically.*

I do not, however, say that every picture must be taken through yellow glass. There are many pictures which can be best photographed without it, but he who has much to do with copying coloured pictures will soon learn by practice if a picture would be best copied with or without the yellow glass, or if not a few experiments will eventually bring him to it. It must, however, be borne in mind that the yellow glass always increases the length of the exposure—often even three times—as even the best yellow plate glass absorbs not only blue light, but some yellow also.

In using stained collodion I usually employ an aplanatic which gives a picture sharp enough even with the full aperture. When the exposure is likely to be long I use a dark slide that has a sheet of plate glass let into the front, in order to prevent the plate from drying, and if required this might be yellow.

The Second Silver Bath.—After the exposure the plates may be developed just like any other wet plates, if the bath be not much affected by the impurities inherent to most dye stuffs, and which cause so-called organic bath flaws to appear after a few plates have been sensitised. These consist partly of crescent-shaped streaks extending from the edges towards the centre. These may be avoided, or at least diminished, by diligently moving the plate about in the bath. If, however, the bath be strongly affected by organic matter, then the only remedy for these impurities is the second bath, which may be called the "developing bath." After exposing, and *before developing*, dip the plate in the following bath:—Silver salt, 50 grammes; water, 500 grammes, nitric acid of 1·22 spec. gravity, 4 to 8 drops. Move the plate about steadily in this for a couple of minutes; the adherent impure silver will be rinsed off by it, and the eosine will be decomposed by the strong nitric acid. The development may then proceed without any risk of the above-mentioned faults showing themselves.

In time, of course, the developing bath will become dirty; it may then be taken into use as a sensitising bath after it has been neutralised, and then acidified again with acetic acid. *This bath also must be tested for acid with litmus before it is taken into use.*

The Development.—The plates are, as a rule, developed with the ordinary developer for wet plates; but the alkaline developer may be used with equal success, and with this advantage—when organic impurities are present fewer stains show with it than with the acid developer. With the acid developer *only one* silver bath is used. The exposed plate is washed first with distilled water, then under a tap for about five minutes, rinsed again with distilled water, and then developed—preferably in a flat dish—with the following developer:—1 to 6 solution of carbonate of ammonia, 2 c.c.; 1 to 4 solution of bromide of potassium, 0·50 of a c.c.; 1 to 10 alcoholic solution of pyrogallic acid, 1 c.c.; water, 30 c.c. With too short exposures the quantity of carbonate of ammonia (which must be dissolved fresh from the glass-like condition) may be increased. —*Mittheilungen.* H. W. Vogel, *Prof.*

(To be continued.)

* In order to make the matter easier to photographers Beyrich, of Berlin, has undertaken to supply yellow plate-glass which I have tested spectroscopically, and also an arrangement for affixing the yellow slide on the inner side of the lens, and also all the other requisites for the process.

THE SPECTROSCOPE AND DEVELOPING-LANTERN SCREENS.

Now that photographic operators learn that they have been unnecessarily injuring their eyesight for years, by the unscientific nature of the coloured screens hitherto in general use for the lantern or window of the developing-room, an apalling reaction has set in, so that in some cases the accuracy of the first principles of science is being denied, spectroscopic facts are cited as untrustworthy, and before long we may hear the zodiac spoken of with disrespect and the equator declared to be a humbug. A spirit of irreverence is abroad in the photographic land.

The well-proved principles of photo-spectroscopy and optics have in no case been in the slightest degree invalidated by any of the changes going on in developing-room illumination, so far as I can see. For instance: let the general avoidance of green light in the past, because of sweeping assertions founded on spectroscopic facts, be first considered.

In the first place, the maximum actinic power of the spectrum does not lie in the green; in the second, a little actinic light in the developing-room does no harm, and may do good if the plates are sufficiently good to have a reserve of the anti-fogging power spoken of by Mr. George Smith; and, in the third place, attention can be advantageously given in developing to the law that the intensity of light diminishes with the square of the distance from its source. So far as I know, none of the persons who have worked with spectroscopic cameras have printed some required detailed tabular results of painstaking experiments, which would have been of special value in photography.

For instance: tabulated experiments as to the spectra produced by differences of time of exposure, all other conditions being the same, would be of value to show how much photographic action is set up in the most active part of the spectrum before the rest of the field produces a developable image, and to show what are the times necessary to drive a developable image through the green and ultra-violet regions. A standard light would have to be employed. The same experiments should be repeated and tabulated, with standard lights of other degrees of intensity. Then some of the series of experiments should be gone through again with sets of plates of varied make and rapidities; for it is only from such data as these to work from that opinions can be formed for practical purposes bearing upon many questions in photography.

With a pure spectrum how long an exposure is necessary to produce a developable image in the red, as compared with those of the green and blue? A bald statement that certain parts of the spectrum produce certain effects on photographic plates is practically almost valueless without tabulated information as to times, intensities of lights, variations in the make of plates, and so on. The effect is comparatively feeble in the green, and if that little require a long exposure to bring up well, one point is unravelled explaining why recent practical results are not at variance with the indications of the spectroscope.

By turning his back to a candle at the end of a room of moderate size the operator can develope a dry plate by candle-light, yet this development by the light of all the rays of the spectrum does not nullify the results of spectroscopic research; it means only that another law has been called into use, namely, that the intensity of light varies inversely as the square of the distance. With a sheet of white tissue paper round the candle the operator might turn his face to the candle at the opposite side of the room and develope the plate, for the tissue paper would but have the same practical effect as if the candle had been removed to a greater distance. A plate of transparent, colourless glass would not have the same effect, for then the photographic differences between transparent and translucent screens come into play. If the operator next put proper colour into his sheet of tissue paper be can work very much nearer the candle; and with properly-selected green and yellow tissue paper—one thickness of each—he can develope ordinary gelatine plates within seven or eight inches of his tissue-paper lantern. A bright paraffine flame in the lantern, instead of a candle flame, or a badly-selected sample of green tissue paper would fog plates under these circumstances; so a little care is necessary in thus obtaining a bright light for developing purposes. W. H. Harrison.

ON THINGS IN GENERAL.

I was very much interested in the perusal of Mr. Lewis Wright's paper on *Coloured and Non-Actinic Light* in this Journal for May 16th. He puts the question of actinic illumination in a manner easily understood, and his dicta, being those of an exceedingly practical man of great scientific attainments, should be well received by the general body of readers of "ours." He points out very properly that there is no such thing as a non-actinic light; yet, I think it may be quite permissible to speak of a non-actinic illumination, the former having a more rigidly scientific import than the latter, which one may refer to the practical effect under given conditions. This discussion, initiated by Mr. W. E. Debenham's valuable papers, which threw an entirely new light upon an old subject, has been most interesting, and if it have done nothing more it will have caused photographers to think about subjects they have hitherto looked upon either as truisms or as out of the bounds of controversial consideration.

Is there any photographer living who (being a user of gelatine plates) cannot cordially re-echo Mr. C. Beckett Lloyd's remark—"If commercial dry-plate makers would expend more of their energies in wrapping the boxes and less in wrapping the plates they would, I think, save a good deal of dark-room bad language." What is more provoking, when closely pressed for time and not a single moment to spare, than have to remove cover after cover from a dozen plates before the slides can be charged? Possibly a piece or two of string has to be cut in addition—a piece of string just too strong to be broken by the hands, which, in the effort to do so, may themselves be very readily frayed and cut in lieu of the string. Dry-plate makers take notice, and do not pack up all your plates as though they were to be used by idiots.

The reports of the lectures at the Royal Institution, given from time to time in these pages, are often very interesting. That by Dr. Odling, the other day, describing some curious properties of hyposulphite of soda, was particularly so. By-the-bye, how confusing to read of hyposulphite of soda as spoken of in a photographic journal and in a chemical journal, two entirely distinct salts being referred to! No doubt many of my readers know quite well what is meant in either case, but with photography under its present scientific aspect the *mélange* should not exist, and might cause considerable confusion under some circumstances. I note that, as a rule, the Editors in their leading articles use the term "hypo." rather than the photographic word in full. If this be done of set purpose the plan is excellent, and may pave the way to the use of the the term "thiosulphate," which is the name given by chemists to the salt used by photographers under the name of "hyposulphite of soda." The latter, indeed, is a developing rather than a fixing agent, and I see no reason why experiments made with it in that connection should not be attempted. Nothing has been done since Mr. Saaman's trials made several years ago, and published in the pages of this Journal. At a meeting of the Parent Society the other day it was very pertinently remarked that some samples of "hypo." contained a considerable amount of sulphite of soda. I believe this to be quite true. I have seen a cask of hypo.—which certainly was kept in a rather warm place, but some of whose contents were being removed daily—show before it was half empty a considerable amount of effervesced salt, which in all probability would be either sulphite or sulphate. Quite possibly it might, in these days of sophistication to meet the demand for cheap goods, be sulphate purposely added as an adulterant.

Mr. Debenham's lecture on photographic optics was particularly interesting, and calculated to impart a large amount of information in a small space, if only it were read. Unfortunately, however, there are such a number of photographers who don't read—that is, in the sense of studying; yet, after all, one ought not to grumble, for there is a far larger proportion of good men (really intelligent, educated men) in the ranks of photography than there were even ten years ago, not to speak of the period when photography eclipsed school-keeping as a refuge for the mentally halt and maimed, and was the thing to fly to when a man had failed in every other walk of life. However, there must be a beginning to all things. It would be rather disappointing to hear, at the above lecture, Mr. Cadett's remarks that, after all, mathematics were not found to be of much actual value, seeing that Mr. Warnerke, who had purposely qualified himself in optical mathematics, found his knowledge of no use—practically, I presume, found the system of trial and error the best to work by. At the same time I take it that the leading opticians, though they may be aided by such a system, do not make any fresh departure without the aid of elaborate theoretical investigations, and, if I mistake not, we shall see the outcome of such investigations in the very near future.

Much sooner than I expect to see any result from Mr. Matthieu Williams's amusing hypotheses. That gentleman has recently been writing for the *Gentleman's Magazine* a disquisition on phosphorescence and illumination, in which he indicates that he looks forward to the time when we shall get something in the nature of extract of glow-worm-light without heat—a pound of wax candle to be converted into a phosphorescing mass that shall not waste ninety-five per cent. of its available energy up the chimney. "Never prophesy unless you know" is Mark Twain's most excellent advice; but I think one might hazard a prophecy that Professor Radziszewski's *Pelagia noctiluca*, which shine so brightly in the ocean, will be without a rival in this respect during the lifetime of any of my readers.

Mr. Norman Macbeth delivered a capital lecture before the South London Photographic Society early in the month, and made one or two very good points. I can cordially endorse his recommendation to study Burnett's work on composition, if my readers can get it. It has long been out of print. I have rarely come across the work in a bookseller's second-hand catalogue, and there are few libraries where it is to be found. I do not know how long the copyright in it exists, or whether it may have expired, but I have seen advertisements of American reprints which could not legally be imported if the copyright still existed. The work was originally published in four parts, one or two only of which would be needed by the photographer. Mr. Macbeth's remarks upon the various subjects known under the name of "composition"—a rather far-reaching term—contain much instruction; but, as usual with artists, he was rather foggy about angle of view and straining a lens. By-the-bye, artists' printers themselves are far from perfect in their arrangements of light and shade. Any academy exhibition will contain a considerable variety of outdoor pictures, illuminated evidently by the lamp or the studio light. But any instruction from a talented man like Mr. Macbeth, who, as his acts show, is so entirely friendly to photography, will be received with pleasure by all true photographers. FREE LANCE.

THE ALBUMEN PROCESS AS APPLIED TO POSITIVES ON GLASS.

[Read before the Photographic Society of Philadelphia.]

BEFORE describing the practical details of the manipulation of albumen plates, it will be well to make the following classification of films prepared with (1) pure albumen and (2) collodio-albumen—the actual sensitive material, or iodo-albuminate of silver (if we may so term it), being the same in both cases.

The earlier experimentalists devoted themselves almost exclusively to the pure albumen film, believing that the presence of collodion injured both tone and delicacy of detail; but as time passed by this was seen to be an error, for collodio-bromide plates were found to possess every good quality, and to be decidedly easier of preparation and development. Nevertheless, we find an article, by Mr. Willis, in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, as late as the year 1875, giving full directions for the preparation of iodised albumen plates without the use of collodion, showing that the older process was still a favourite. The directions there given may be condensed as follows:—A mixture of the white of egg, water, and iodide of ammonium is beaten to a froth and allowed to liquefy again, after which it is applied directly to clean glass plates. A piece of broomstick, about a foot long, is tipped at one end with a small piece of gutta-percha softened by heat; this is applied to the back of the glass until it adheres, and the iodised albumen having been poured on the face of the glass and guided out to the corners by a glass rod, the stick is rapidly twirled between the palms of the hands so as to throw of any excess and leave a thin, uniform coating. The plate is now dried in a closed box, to prevent any dust from falling upon it, and is then sensitised in an aceto-nitrate of silver bath, after which it is washed, dried, and exposed. The development is conducted by pouring a saturated solution of gallic acid into a glass pan supported over a sand bath or other convenient source of heat, and immersing the exposed plate, previously adding a minute amount of nitrate of silver. The image appears in about twenty minutes, and the plate is fixed in hyposulphite of soda containing a little chloride of gold, which tones the image at the same time.

Here then, it will be seen, we have an albumeno-iodide of silver alone. The tedious development and troublesome coating of the plates—during which, by-the-bye, the greatest care must be taken against dust—have probably been the chief reasons why this process was never a universally-popular one. The process now to be described fulfils, I believe, all the desiderata in an albumen positive, and, so far from being troublesome to work, is remarkably easy. I may mention that it is not a dozen years since this process was sold to the professional photographers of Philadelphia at quite a high price, and was used by a number of them with great success. It was given to me shortly after by a friend. The directions are substantially as follow:—Glass is cleaned, coated with any good bromo-iodised collodion, and then washed under the tap. While still wet, it is flowed with iodised albumen, and then dried. It is then sensitised in aceto-nitrate of silver, washed, dried, and exposed. The plate is developed in the hand with acid pyro. and a little nitrate of silver, using a spirit lamp to keep the developer about blood warm.

Thus, it will be seen that, while identical in theory with the process as described by Mr. Willis, this one is far less laborious. The coating of the plate is easily and quickly done, and seems not to require any further precaution against dust than such as any good operator would instinctively take. The development is by no means as tedious, being complete in three or four minutes, unless the plates have been undertimed, or the developer allowed to get chilled. It is also simpler and more economical than the Taupenot process, from the fact of only one silver bath being used. Still, it has its drawbacks in being very insensitive when developed as described, and in the film being so nearly transparent that, in the event of over-timing, solarisation is almost sure to occur. Another trouble which sometimes makes itself painfully felt is blistering or slipping of the film. This, however, can be entirely got rid of by using no albumen substratum on the cleaned glass, and, instead, giving each plate a rub off with powdered French chalk, applying the collodion directly afterwards. A number of experiments recently made to test this special point prove it beyond doubt to my mind.

All things considered, however, the Taupenot process is the most generally useful for slide-making. Although the labour of preparing the plates is great, undoubtedly, still it has this in its favour, that the manipulations need not—indeed, ought not to—be done all at one time; and I feel safe in saying that anyone, after a few trials, will be surprised to see how naturally and easily the process divides itself up, as it were, into a series of operations that may be done at any convenient time.

Everyone knows the exquisite quality of the French slides—both in tone, in detail, and in brilliancy or perfect freedom from deposit. While I do not for a moment presume to place my own efforts in comparison with the work of Levy and other famed Parisian operators, I have still, in the course of some experiments very carefully made during the present winter, noticed a number of points in which my own work resembled the French so far that I feel convinced the latter are made on Taupenot plates and toned by mercury, followed after a careful washing by cyanide of silver. I have some reason to believe that the development, instead of being conducted with pyro., is done with gallic acid by the aid of heat, and the plates developed film side down. There are decided advantages to be gained by this method. In the first place, the development of an albumen plate of any kind, but particularly of those such as the Taupenot, where albumen is the principal constituent of the compound film, must be *slow* when compared to other plates if the finest result be desired. This is a cardinal point in the management of albumen films, both positive and negative. In the next place, the quantity of free nitrate of silver added to the developer must be very small, particularly at the beginning of the development. The solution being thus excessively weak, heat forms a useful adjunct to the process, which would otherwise drag along in a most tedious manner. Now, when plates are developed in the hand over a spirit lamp, the fingers get cramped when the development is so long, and the temptation to add a little additional silver is well-nigh irresistible. In the dish this, of course, would not apply, and I may here say that nothing but the impossibility of obtaining the proper kind of glass pan, with ledges on the bottom to support the plate, has prevented me from trying the older-fashioned method. Any article other than glass can hardly be recommended for gallic acid development; for the addition of the silver makes a fluid highly susceptible of decomposition by contact with the slightest impurity. This was alluded to as long ago as the year 1858, by Hardwich.

The blistering of the film, of which I have spoken before, is apt to cause the loss of many plates in the hands of a beginner. It depends partly upon the condition of the substratum (or, rather, of everything which underlies the albumen film proper) and partly upon the albumen itself. It should not be forgotten that the whites of eggs vary in glutinosity, some eggs yielding an albumen so thin that it may be filtered with ease, while that of others is a stiff, gummy mass that requires hard beating in order to become workable. Under any circumstances, however, when albumen dries it becomes a dense, horny, impenetrable pellicle of great contractility, so that it is not at all strange that the tension on the film, produced by its desiccation, should often be sufficient to blister the film, or even to draw it entirely off the glass. It will, therefore, always be well to add (say) sixty or eighty grains of white sugar, or an equivalent proportion of molasses or honey, to the iodised albumen. This modifies the horny structure of the latter, and will often be a complete cure for blistering. If the plates should be exceptionally obstinate, the application of French chalk, as before alluded to, will effect it. In comparing the process by iodised albumen with the Taupenot, it will be seen that in the former the collodionised plate is dipped *into water* before the iodised albumen is flowed on. Evidently, any substratum previously applied would thus be dissolved away, and might as well not be there at all. Some operators have doubtless depended upon the coagulation of the substratum by the alcohol in the collodion. This is a false idea, a layer of *dry* albumen not being susceptible of such treatment. The attempt has, indeed, been made to coagulate albumenised papers by dipping them into a dish containing alcohol, and partial success obtained; but the difference between a layer of albumen on a spongy body like paper, which could absorb and retain a large quantity of spirit, and a thin layer on glass, approachable by only one of its surfaces, is manifest. Now, in the Taupenot, or any other process where the plate is dipped into the silver bath before being washed, the silver salt—one of the most efficient coagulators of albumen known—has an opportunity of penetrating to the substratum and fixing it by rendering it insoluble.

To obtain the best results with any kind of albumen plates, they should not be kept long after sensitising in the aceto-nitrate. Three or four days in winter, or twenty-four hours in summer, would be an extreme limit. But it fortunately happens that we possess in gallic acid an agent which confers almost unlimited keeping qualities upon the film, provided that it be applied immediately after the aceto-nitrate of silver has been washed off. The washing in this case must be very thorough, any traces of silver which remain causing a red stain. The sensitiveness is decidedly lessened by the gallic acid—at least thirty per cent.

The sensitiveness of albumen plates will vary with the method of preparation, and the presence or absence of a final wash of gallic acid. As previously mentioned, pure albumen films, even without gallic acid, are very slow if developed with acid pyro.; and when gallic acid is the developer the process is so lengthy that it becomes impossible to do it in the hand. But a freshly-sensitised Taupenot plate is quite the reverse, particularly when alkaline pyro. is used at the beginning. Under favourable circumstances it would be quite feasible to take *quasi* instantaneous views on these plates—that is, street views and marine studies. This is also confirmed by M. Ferrier, the predecessor of Levy in Paris, who ranks Taupenot plates as the very best of all known forms of dry plate, suitable for both professional and amateur photographers, and unexcelled for keeping qualities when treated with gallic acid. It will be understood that the gallic acid wash is only intended for plates that have to be kept for a long time; but when lantern slides are to be made it is better dispensed with, and the plates used as soon as possible after sensitising, the tone of the image being finer without it. For negatives this is not of so much importance.

A deposit is apt to form on plates that have been long kept, or when the developer is over-heated or the process too much forced. This may easily be removed by gently rubbing the film with a ball of soft, clean cotton, thoroughly wet, holding the plate under the tap. The coagulated albumen is hard enough to bear this treatment perfectly.

Those who are familiar with the published formula for the Taupenot process will notice two differences in what follows:—First, the addition of white sugar to the albumen, the reason for which has already been given; and, second, the wash of fifteen-grain iodide of potassium, which is applied to the film immediately before the albumen. It might very pertinently be asked—Why is an aqueous wash of iodide, immediately preceding the application of the albumen, loaded with the same salt necessary? In order to answer this satisfactorily, it must be constantly borne in mind that the Taupenot film is *double*—that is, an albumeno-iodide of silver is superposed on a collodio-iodide. Now, in order that the alkaline iodide may enter thoroughly into the pores of the collodion film, it is necessary first to apply it in a form more capable of working its way in than the viscid, thick albumen, which always has more or less tendency to remain on the surface. Mr. Hewitt was the first to notice this fact, and to introduce the aqueous wash, and I consider it a very important improvement in the process. If the albumen were directly applied we would have to expect more or less irregularity in the film, and perhaps partial sensitiveness to daylight, which is not the case in plates prepared by the following formula; in fact, all the manipulations up to the second sensitising may be done in white light—a great practical advantage to the operator desirous of having clean, well-coated plates. The iodide wash completely obliterates whatever effect the white light may have had on the collodion film.

Before concluding I will give the formulæ for both processes. The iodised albumen may be the same in both, and I have found no reason to alter the formulæ which were given to me by Mr. Hewitt some years ago.

Iodised Albumen.

Iodide of potassium	35 grains.
Water	½ ounce.
Tincture of iodine	3 drops.

Dissolve and add to five ounces of white of egg, taking care that there is no yolk present. Beat to a froth, and let stand until liquefaction has taken place; then add from three hundred to four hundred grains of white sugar, and one-half drachm of ammonia. Keep it in small bottles filled to the neck and tightly corked, adding to each bottle a piece of camphor the size of a pea. If stored in a cool place it will be good after some weeks.

For the simple albumen process the plates are coated as before described, and well dried. For the Taupenot process the glass (cleaned and albumenised as usual) is coated with a rather thin and ripe collodion, dipped in the ordinary silver bath, and then washed free from silver; after which it is flowed with a fifteen-grain solution of iodide of potassium and drained. It is then treated with two portions of iodised albumen and dried.

Aceto-Nitrate Bath.

Nitrate of silver	400 grains.
Water	10 ounces.
Glacial acetic acid	1 ounce.
Nitric acid	2½ drachms.

The bath should not be exposed to daylight.

Development.

Pyrogallic acid	40 grains.
Glacial acetic acid	I ounce.
Distilled water	20 ounces.
Citric acid	15 grains.
(*a*) Nitrate of silver	10 grains.
Water	I ounce.
(*b*) Nitrate of silvor	20 grains.
Citric acid	30 ,,
Water	1 ounce.

Plain albumen plates are developed with the above solutions by the aid of heat. I rather prefer to use the second formula for silver solution (*b*), in spite of the large amount of acid. The development being lengthy, there is less risk of staining if there be a full amount of acid present. A few drops of the ten-grain solution may be added if more intensity be desired. It is well to provide each bottle with a dropping-tube, so as to be able to measure the amount exactly. A *single drop* of either is enough to start the development.

In the case of Taupenot plates the detail should first be brought out by a two-grain pyro. solution containing one drop of a saturated solution of carbonate of ammonia to each quarter-ounce, the strength being afterwards brought up with the acid pyro. and silver.

Fixing and Toning Bath.

Hyposulphite of soda	6 ounces.
Water	1 pint.

Dissolve, and add four grains of chloride of gold dissolved in two ounces of water, throwing in a small lump of white chalk to neutralise acidity. All traces of the developer must be washed off before laying the plate in this bath.

Toning and Intensifying.

(*a*)	Bichloride of mercury	1 ounce.
	Chloride of ammonium	1 ,,
	Water	4 ounces.
(*b*)	Cyanide of potassium (pure)	20 grains.
	Nitrate of silver	20 ,,
	Water	1 ounce.

Dissolve the silver and cyanide separately and mix, stirring until the precipitate redissolves. There must be a slight excess of cyanide in the solution.

The plate, after being fixed and washed, is flowed with the mercury (*a*), diluted *ad lib.*; then, after a *thorough washing*, followed by the cyanide of silver (*b*), and again quickly washed to prevent loss of intensity, which will occur if the solution be left on too long.

ELLERSLIE WALLACE, JUN.

FOREIGN NOTES AND NEWS.

DIFFERENCES IN READINGS OF THE PHOTOMETER.—A CHEAP SUBSTITUTE FOR GROUND GLASS.—A NEWLY-PATENTED LICHT-PAUS PROCESS.

IN the *Bulletin de la Société de la Photographie*, M. de La Noé said he had found that, when examining a photometer in the morning or in the evening, one would read off higher numbers than at midday, because at the latter time the eyes are more affected by the dazzling brilliancy of the midday light, and, therefore, are less sensitive than in the morning or evening. He also declared that an observer who had remained for a-quarter of an hour in the dark, and whose eyes consequently had been rested, could recognise the twentieth degree on an exposed photometer, while a person who had been working in bright daylight could only read as far as the fourteenth degree. He, therefore, considered photometers based on the recognition of the commencement of an impression of light as unreliable.

In commenting on the above, the editor of the *Mittheilungen* remarks that errors of six degrees, such as that cited, would certainly render the photometric quotations totally unreliable, since the intensity or quantity of light required to render the number twenty visible is five and a-half times as great as that required for number fourteen. The error is not, however, actually nearly so great. Surely it must depend a good deal on the eyesight of the individual observer. The editor has, however, often made the experiment of causing two persons—one of whom had been working for several hours in a darkened room and the other in a bright light—to read off the same photometer, and the difference between the two readings was at most one degree.

In the *Deutsche Photographen Zeitung*, Herr Schlechter, of Carlsruhe, suggests a simple plan for obscuring the glass of the studio, which he has seen used by gardeners for keeping off the too bright light of the summer sun from the contents of their greenhouses. He tried it on his glass-house and found that it answered very well. Some glass-houses, where the roof or sides require to be as transparent as they can be made in winter, yet require to be obscured at least during the height of summer; for this purpose many persons paste thin tissue paper upon the panes, and others get a house-painter to paint them. Herr Schlechter's plan is to pound down some chalk and mix it with milk to any desired consistency and then apply the mixture with a large flat brush. One coat would last the whole summer and be extremely cheap. The idea is very good, and the present writer has seen something similar successfully carried out—only in this case the coat of obscuring mixture was applied outside the glass instead of inside, and consisted of buttermilk and whiting laid on with a white-washing brush—outside the glass roof of a factory. The reason why it was put outside was obviously to save the great expense of erecting the high scaffolding that would have been required had the inside of the glass been coated or had blinds been put up. There was the further advantage that no trouble had to be taken to remove the whiting, as the sun and rain had effectually removed it before the dark days of winter set in; but, of course, as the photographer would need all the light he could get in winter he might give the weather a helping hand in the removal, with advantage as regards the appearance of his premises.

Herr Nickel, of Chemnitz, has patented a licht-paus process in the German Empire. The process is intended to reproduce by lichtpaus, in blue lines upon a white ground, any kind of a drawing by using the well-known licht-paus paper, which is sensitised by treatment with citrate of iron and ammonia, and red prussiate of potash. The process is based upon the production of a negative copy of the drawing to be multiplied, by using as follows a special licht-paus fluid:—Take some filtered gum arabic and mix it with acetic acid, in order to render it fluid and prevent it from spoiling; then add a little dissolved soap, in order that the lines drawn by this mixture may not be brittle when dry. Add Indian ink to this mixture until a drawing made with it is quite visible. Make a copy in the usual way, with this ink, of the drawing to be copied, drawing upon the rough side of the ordinary paper. Then with the finger rub upon the same side of the copy as much common, soft, black chalk as the paper will take on. The chalk had better be previously pulverised. When all that has been done the drawing is laid in water and then carefully rinsed. By this means the whole of the lines drawn with licht-paus ink dissolve out and disappear, leaving the drawing in sharp, white lines upon a black ground. If this negative-copy is to be often used, it is recommended that it should be fixed by brushing it over with a broad hair-pencil dipped in spirit varnish, or by coating it with a solution of gum arabic to prevent the black chalk from spreading over the white lines. When such a negative has been made one may proceed to throw off an unlimited number of licht-paus pictures by means of the sensitive blue licht-paus paper, which gives blue lines on a white ground, by which a further carrying out of the licht-paus by means of colours is facilitated.

No. 7,974.—"Producing Printing Plates or Blocks by Photography." H. J. HADDON; a communication from Henrich Riffrath, Gladbach, Germany.—*Dated May* 20, 1884.

IMPROVEMENTS IN THE CONSTRUCTION OF PHOTOGRAPHIC CAMERAS.
Specification by Messrs. SANDS AND HUNTER.

THE object of this invention is to render cameras adjustable in a superior manner and to afford increased facilities for working the same, by means of a double-swing action or cradle.

In carrying out our invention we so mount the cradle or swing action that it can be placed at any part of the base-board and at any angle thereto that may be required. The camera can be placed upon the cradle either horizontally or vertically. We use either a rigid base-board or one extending either at the front or back by means of a screw, rack, or clamp; upon this base-board is placed the cradle or double-swing action. To facilitate the rocking and swinging of the cradle or camera, we introduce a new double action rack-and pinion movement, one pinion working through the head of the other, or by two or more separate rack-and-pinion movements, or by screw movements. This is arranged in the following manner, viz.:—

The cradle or double swing is constructed of two or more slips of wood or metal, the top one being slightly rounded underneath. It is supported by means of two pins, one at each end, passing through a piece of metal fastened to one of the under-pieces; if the under-piece is of metal it is turned up at each end, to support the upper piece or rocker and receive the pins. The under piece of wood or metal may be connected with the base-board, or fixed to another slip of wood or metal made adjustable to the base-board.

These slips of wood or metal are made to move in their separate directions by a double-headed rack and pinion, one pinion working through the head of the other, the rackwork being attached to the upper and lower pieces. By turning the head of one pinion or screw the upper slip of wood or metal can be rocked backwards or forwards, thus giving the double-swing action.

The same action is obtained by means of clamps, one clamp being attached to the top rocker, the other to the under-moving piece, which enables them to be moved or fixed in any direction, the clamp passing through slots in the side brasses. This method of moving the cradle being in substitution for the pinion or screw movements.

The camera can be fixed on this cradle either horizontally or vertically, by means of a spring screw, nut, bolt, or any other convenient means, and can thus be made to swing in any direction. The front of the camera can also either be fixed or made removable to any part of the base-board, and the bellows is also so arranged that it will revolve on the front, or can be taken out and turned in any direction, for which purpose the front is held in position by means of a circular flange, which permits the rotary movement to take place as on a fixed centre. [Here follows a description of certain drawings.]

Our said invention can be adapted to any suitable camera.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is—

1. The method, means, and appliances of and for adjusting cameras by a double-swing action cradle, substantially as hereinbefore described and shown on the drawings.

2. The use of clamps and other arrangements for effecting such double-swing action as hereinbefore described and shown in *figs.* 1, 2, 3, 4, 5, and 6, or any mere modification thereof.

3. The use of the pinions, racks, and other arrangements for effecting such double-swing action as hereinbefore described and shown in *figs.* 7, 8, 9, and 10, or any mere modification thereof.

4. The several and respective arrangements and appliances to cameras, together forming our improvements in the construction of photographic cameras, substantially as hereinbefore described and shown in the drawings.

Our Editorial Table.

"DIE COLLODION-VERFAHREN" and "DER SILBER-DRUCK."
By E. LIESEGANG, Ph.D.

WE have received the eighth editions of the above two popular works. The mere fact that these little books have reached an eighth edition speaks much for their practical character, but a dip within the covers will show still more their real utility. It may be supposed by some that collodion processes are out of date and out of use, but such we know is not the case; and those who still employ wet collodion, or who wish to be instructed in its practice, will find in Dr. Liesegang's *Die Collodion-Verfahren* a safe guide in every department, even to collodion emulsion.—*Der Silber-Druck* is an equally valuable guide through all the different branches of printing, whether on albumenised paper upon opal glass or by development—by artificial light as well as by daylight. The surrounding operations—retouching, mounting and finishing—are also well treated, and notes on artistic matters make the work complete.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the monthly technical meeting of this Society, held on Tuesday, the 27th instant, the chair was taken by Captain W. de W. Abney, F.R.S.

Mr. T. Sebastian Davis said that for some time past he had been in a difficulty from the fact that his negatives had given much thinner images than before, and had required considerable intensification. The negatives even then wanted sparkle. This he attributed to a want of transparency in the shadows as well as to the thinness of the image. Someone had suggested that these difficulties were due to a want of thoroughly washing the emulsion. He had, therefore, washed more—very thoroughly, in fact—but found no gain from that proceeding. In answer to questions as to the formula used he (Mr. Davis) said that he used rather a large quantity of acid—equal to something more than half-a-minim of pure hydrochloric acid for each ounce of finished emulsion to be made. For a ten-ounce batch he used 200 grains of nitrate of silver, 150 grains of potassium bromide, and ten grains of chloride of ammonium. This he digested with eighty grains of gelatine for an hour at a temperature of 160°. Afterwards 220 grains more of the same gelatine (Heinrich's) were added. The emulsion was quicker than that he formerly obtained when he was getting greater density.

Mr. W. E. Debenham and Mr. A. Cowan remarked that they should have expected an emulsion so prepared to be decidedly slow.

Mr. Davis continued that he had got greater speed since he had adopted the method of mixing-in the silver solution drop by drop instead of the usual method. The gelatine was Heinrich's ordinary kind for photographic use—not an extra-hard kind, which was also made.

Mr. Léon Warnerke had tried both kinds without finding much difference.

The Chairman had made a long series of experiments, and found that with a digestion process the more gelatine was added the quicker were the plates, but this was not so with the boiling process. He asked if Mr. Davis's plates showed the image strongly at the back.

Mr. Davis replied that they did not with his usual development. If he much prolonged the development the image did appear at the back, but at the same time he got fog.

The Chairman remarked that there was an unusually large quanitity of hydrochloric acid employed, and that that acted upon the gelatine. He would recommend the use of a small trace of hydrochloric acid only, and the addition of free iodine to obtain clearness.

Mr. Warnerke considered that equivalent to using hydrobromic acid.

The Chairman said that iodine did not liberate hydrobromic acid. He had tried hydrobromic acid and did not like it at all.

Mr. Davis said that, hoping to obtain density, he had tried the addition of gallic acid to the emulsion; but it was not beneficial, as it had been in the collodion process.

The Chairman inquired how long Mr. Davis took to develope.

Mr. Davis replied that the development was rather rapid. The image began to appear in about twenty seconds, and development was complete in two minutes. He used two grains of pyro., two minims of ammonia, and half-a-grain of bromide.

Mr. Debenham suggested the use of a much larger proportion of bromide—at least as much as of pyro., if not more.

The Chairman said that he generally used half as much bromide as pyro., but he believed that the use of equal parts was safer. He inquired the sensitometer speed of Mr. Davis's plates.

Mr. Davis replied that they were 16.

The Chairman asked whether Mr, Davis had tried changing his gelatine.

Mr. Davis had used several kinds, which he mentioned—amongst others, Swinburne's isinglass.

The Chairman believed that that was a gelatine.

Mr. Warnerke inquired why so?

The Chairman replied on account of its price.

Mr. Warnerke said that at the recent Fisheries Exhibition isinglass was sold at eighteenpence per pound. That made from the bladder was expensive, but isinglass or fish glue was now made from the entire fish, and could be sold at the price mentioned. This cheap kind was not, however, adapted for photographic purposes. A test for isinglass, to distinguish it from gelatine, was its appearance when soaked in cold water. Gelatine sometimes became a little cloudy-looking, but isinglass acquired a characteristic bluish opalescence. The character of the gelatine used had a considerable influence upon the emulsion; but, unfortunately, it happened that two batches from the same maker professing to be of the same kind would differ considerably.

Mr. Davis inquired whether ammonium or potassium bromide was to be preferred in making emulsion.

The Chairman replied that the potassium salt was to be preferred, and gave greater density.

Mr. Davis said that, having been one of the committee to select the best process for awarding the Paget prize, he remembered that the successful candidate, Mr. W. J. Wilson, strongly recommended the use of a certain make of potassium bromide.

Mr. T. Bolas said that commercial samples of bromide of potassium varied much in their constitution. Most samples coming from Germany—at all events some time ago—contained traces of iodine. It was of importance to know precisely what were the chemicals one had to deal with, and he would recommend the preparation of a pure bromide by fractional decomposition of the salt. For ordinary commercial purposes absolute purity of the bromide was of no consequence, therefore one must not expect the makers to supply it as pure as it should be for photographic purposes.

The Chairman said that he had known bromide of potassium to contain as much as twenty-five per cent. of chloride. It could be freed from iodide by the addition of a very small quantity of nitrate of silver solution. The iodide contained would go down as iodide of silver, and the amount of silver solution being known, the strength of the bromide remaining would also be known. With bromide, as now supplied by English dealers, he thought no trace of chloride would be found.

Mr. Bolas considered the question of the purity of the commercial bromides, and the effect of what other haloids might be contained in them as impurities, was so important to photographers that the Society would do well to take the matter up.

The Chairman thought that the time had come for such matters to be taken up by sub-committees, and it was arranged that the proposition to deal with the question in this manner should be brought before the next meeting of the Council of the Society. He asked Mr. Davis whether he had examined the image on his present plates with a microscope?

Mr. Davis had done so, and found a grain.

The Chairman had found that in a dense negative the grain in the plate itself before development and in the developed image was fine, but in a plate which gave a thin image the grain was coarse. For examining the ten-thousandth of an inch an inch power was sufficient; but to see grain of the fineness of one-hundred-thousandth of an inch a quarter-inch power and high magnification wth the eyepiece were necessary.

Mr. Warnerke inquired whether there was any difference between the grain given with pyro. and that with ferrous oxalate.

The Chairman said that the ferrous oxalate grain was coarser.

Mr. Warnerke stated that in the March letter of the Chairman to the *Bulletin Belge* there was a riddle, which he asked the Chairman if he was prepared to solve. In that letter the reader was directed to dissolve some magnesium wire in oxalate developer, and then see what the result would be.

The Chairman was not prepared to say.

Mr. Warnerke said the result was that the developer was improved, and brought out details which would not be brought out without the magnesium.

Mr. Bolas remarked that ferrous oxalate solution always contained some traces of the ferric salt. The magnesium would reduce this to the ferrous state. Zinc would have the same effect.

The Chairman observed that ferric salt acted as a restrainer, and if some of an old, but unused, oxalate developer were added to a fresh solution the mixture might be employed without the addition of any bromide.

Mr. Warnerke referred to the tin tubes—such as colours and scents were sold in—and said that they were convenient for two photographic purposes. One that he employed them for was the keeping of developers air-tight ready for use; another use was for keeping ink in for collotype or other printing-press process. He (Mr. Warnerke) also inquired whether anyone could speak of an accelerator which bore an English name and was favourably known on the continent. He had tried it and found that it actually did what it professed to do. It had an acid reaction, and smelt of acetic acid. When a plate had had only one-third of the proper exposure it would, after immersion in the solution, develope as if correctly exposed, and gave, if anything, a brighter and better picture than with longer exposure without the accelerator.

Mr. Bolas referred to an experiment wherein plates exposed five hundred times too much were developed after an immersion in bromine water. This suggested the use as an accelerator of some absorbent of bromine.

After a short discussion on gas burners for heating purposes the meeting was adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on Thursday, the 22nd instant, Mr, J, H, Hare occupied the chair.

A letter from the President of the Balloon Society of Great Britain was read informing the members of the first of the balloon garden parties, which was to be held on the 31st instant, and suggesting that some of the members should attend with their cameras to obtain photographic records of the occasion.

Mr. W. E. Debenham showed a contrivance for changing and developing plates when away from home. It consisted of a tin dish with slanting sides like a baking-dish, about thirteen inches by eight at the bottom, and an inch and a-half deep. A folding frame of stout wire covered by two thicknesses of black twill was placed standing on the bottom of the dish, and rising to a height of about ten inches. There were sleeves in the covering to admit the hands, and the wire frame was bent at each end into a curve so as to allow greater freedom to the movements of the arms and hands. The dark slide and the box for changing or the dish for developing were first placed in the tin tray or dish, and the cover then erected over them. A piece of elastic sewn into the hem of the cover served to keep it in place over the side of the tray. The hands were then introduced through the sleeves, and the changing or developing conducted in darkness. Mr. Debenham said that although a plate developed in darkness could not be humoured to suit under- or over-exposure, still it would come out properly if correctly exposed, and, if not, it would serve as a guide in exposing others. It was very desirable, when away from home, to know whether the exposures that were given were about right or not. He had recently used the appliance with success when photographing machinery in an engineering workshop. Having got the exposure by developing one negative, for the others, to be taken, he had merely used it for changing plates. Another use for the appliance was for demonstration before a meeting. To illustrate this a transparency was printed by the light of magnesium wire and the plate developed. The development was, of course, reckoned by time. With the solutions he was using and the temperature at the time a minute and a-half was right in this respect. When the wire frame and cover were taken down they were carried inside the dish.

Mr. A. L. Henderson thought that such a contrivance was unnecessary, as one should be able to judge sufficiently well the time of exposure required. He would rather take half-a-dozen plates with him than be hampered with such an arrangement.

Mr. A. Cowan pointed out that if there were several subjects to be photographed it would be inconvenient to have to carry half-a-dozen plates for each in order to ensure correct exposures. He thought it was desirable to have a test apparatus.

Mr. Henderson, commenting upon the differences existing between Warnerke sensitometers, said that a professional plate-maker had that day told him that the one in Mr. J. Cadett's possession registered two degrees higher than his (Mr. Henderson's).

Mr. C. Ray Woods said that a gentleman of his acquaintance had a sensitometer which registered several degrees higher still than Mr. Cadett's—he thought three degrees.

Mr. Henderson remarked that, at the risk of being thought unscientific, he would produce the results of some experiments he had made in the direction of dark-room illumination. He showed two plates, which he said had been cut originally from the same plate, and exposed under the same sensitometric screen for the same length to the same lamp-flame, covered with a screen of aurine. The one showed numbers indicating an action six times as great as that of the other. The difference was that in the one case the light had been made to pass through a diffraction grating, and in the other through two thicknesses of glass, with the same sized opening as that of the grating, and slightly obscured, to render the glass equally obstructive to the light, so far as the eye was concerned. To the interposition of the diffraction grating he attributed the great immunity from the effect of the light of the lamp upon the plate. At the next meeting the lamp and arrangements should be produced, and the members could repeat the experiments themselves.

Mr. C. Darker said that light might be manipulated in more ways than photographers thought. In answer to a question as to how large diffraction gratings could be made he said that Mr. W. G. Letsam had one of five inches square, but of that size they would be exceedingly expensive.

Mr. Ray Woods said that Professor Holmes had made several very large ones. There were some at South Kensington measuring six inches by two.

The Chairman showed an instantaneous shutter the opening of which was achieved by an elastic band, the hook engaging it being thrown out of gear when the slide was raised to the highest point. It then either reclosed by falling with the speed induced by gravity, or by means of a metallic spring which, being pushed in more or less, acted with more force and rapidity.

At the request of the members, for the purposes of demonstration, Mr. Debenham presented the Association with the changing and developing appliance that he had shown.

Correspondence.

SULPHO-PYROGALLOL.

To the Editors.

Gentlemen,—The experiences of Mr. J. W. Thornton and of Mr. Washington Teasdale, contained in the report of the meeting of the Leeds Photographic Society on the 1st instant, are so contrary to any of our own that we wish you to permit us to make this statement, since we consider that an erroneous impression would tend to be given of the quality of our manufacture were the remarks permitted to pass unnoticed by us.

We can only presume either that a trace of iron or some foreign matter inadvertently obtained access to the liquid at some time after the bottle was opened, or that the solution, as supplied, was diluted with water by the users.

A great number of your readers could report very differently of the sulpho-pyrogallol made by—Yours, &c., The Platinotype Co.

29, Southampton-row, W.C., May 23, 1884.

THE NEW DEVELOPER.

To the Editors.

Gentlemen,—I think that if my letter *re* the new developer has not become ashes, you will find that I added one *drachm* of the carbonate of soda, and not one *ounce*, as I am made to say in your last week's issue.

If anyone has tried the developer and used the ounce they will probably have been uncomplimentary in their language respecting new developers and amateurs.

I have today obtained some very good 10 × 8 negatives with the formula.—I am, yours, &c., W. Bassano.

Haden Cross, Old Hill, May 24, 1884.

A CORRECTION.

To the Editors.

Gentlemen,—A reference is made in one of the articles, in your issue of last week, to a contrivance for liberating a drop shutter exhibited by me at the London and Provincial Photographic Association, in which water takes the place of air.

I acted simply the part of the exhibitor, and whatever credit is due for this ingenious exchange of the elements should be given to Mr. Sands, of the firm of Sands and Hunter, Cranbourn-street, W.C.—I am, yours, &c., A. Mackie.

7, Goldhurst-road, N.W., May 21, 1884.

HEAT-RESISTING CAMERAS.

To the Editors.

Gentlemen,—Photographers in India are often confronted by a difficulty unknown to their brethren working in cooler climes—I refer to the splitting of the camera and dark slides. The latter, especially, become warped into all sorts of shapes directly the warm weather begins, and I find that instruments by first-class makers suffer as much as any others of cheaper make.

I have been told that cameras and slides are now made in England of compressed paper, which will neither warp nor split. Can you or any readers of your interesting Journal tell me who the firm is, that I may give them a trial? Perhaps the Willesden paper one hears of so much now might be made up into slides, or even into cameras, if sufficiently-thick sheets are procurable.

This difficulty of warped woodwork has bothered me more than all the usual troubles one expects in a hot country, and I should be most thankful for any information which would enable me to avoid it.—I am, yours, &c., H. G. S.

East Indian Railway, Cawnpore, May 3, 1884.

[Our information on this subject is at present limited to what we receive from our advertising pages.—Eds.]

Notes and Queries.

Frank Davidson suggests that it would be useful if we were to give one or more articles upon binocular photography and the preparation of transparencies for the stereoscope. We shall consider the matter.

In reply to "B. F. P.," who inquires which of two lenses is the better—one having a fixed stop of an inch and three-quarters, the fixed stop of the other being a half-inch less. We would say that if, when working with the apertures above mentioned, both define equally well, then the former is to be preferred.

Can our Editors or any correspondent inform me how the ink-photo. is produced? Is it a mechanical transfer from a negative? and, if so, is the process patented? Or is it a drawing on a grained surface?—Puzzled."——Perhaps some of our correspondents who may know all about this process will reply. We are in a position to say that it is not patented.

"What is the best way to photograph a somewhat frisky horse who *will* persist in tossing both head and tail when I desire to uncap the lens?—Charles F. Reid."——Let our correspondent try the effect of getting a friend to blow a loud and shrill whistle just when he is ready to expose. This will startle the horse for a moment, and cause him to remain perfectly still for the time requisite to make a good exposure.

"Would you kindly advise me as to the most suitable lens for outdoor work—to take animals, groups of children, or suchlike? I have a Ross's rapid symmetrical, but in our smoky atmosphere of Lancashire it is too slow.—G. MacG."——In reply: The lenses next exceeding the "rapid" class in rapidity of action are the "D" series of Dallmeyer and the "universals" of Ross and Co. If these prove to be still too slow, the ordinary portrait lens must be tried.

George Melcomb asks:—"What is a panoramic photograph?" and wishes that we would give him, what he pleases to term a definite answer. Well, this is a matter upon which a good deal may be said *pro* and *con.* If our correspondent desired to know the difference between plane and panoramic projection we should not experience much difficulty in replying; but to define a panoramic photograph is a very different matter. Roughly speaking, we might say that if, as some artists assert, an angle of sixty degrees is all that ought to be included in a picture, anything extending beyond that is entitled to be classed as panoramic, more especially if the top and bottom be removed to such an extent as to impart a decidedly elongated appearance to the photograph. If the angle included be over 100° we should unhesitatingly relegate the photograph to the panoramic class.

C. Jones says:—"The death of Mr. H. Baden Pritchard, of your weekly contemporary, prompts me to ask if it would not be worth while for any enterprising photographer to make a collection of a few dozen portraits of men whose names come before photographers with more or less frequency? Such a collection would be of great interest. It would, I think, sell sufficiently well to prove remunerative, and I do not imagine that any difficulty would be experienced in the compilation. What think you?"——In reply: We pass on the suggestion to our readers.

"I have often heard of a 'globe' lens; kindly inform me what it is, where it is to be obtained, and what are its functions.—Geo. Thomas."——In reply: The globe lens is not now manufactured. It may be designated the parent of the doublet species of lenses at present in general use, although we are aware that this distinction is open to be disputed. It is a symmetrical combination which was invented by Harrison and Schnitzer, of New York, and patented by them in 1862. It has been entirely superseded by improved forms and cannot now be obtained.

An Old Correspondent writes:—"I have access to unlimited supplies of lemon juice. Can you inform me of any method by which I can crystallise the citric acid contained therein so as to be able to retain it in the usual solid form?"——In reply: Saturate the lemon juice with chalk or whiting, and when the solution has become neutral to test paper wash the citrate of lime with hot water, and treat with dilute sulphuric acid, by which sulphate of lime is formed and citric acid set free. This is then crystallised. We have here given merely an indication of the principle underlying the preparation of the acid; there are details into we cannot here enter.

T. D. says:—"Will you kindly, through the Journal, inform me of the best keeping formula for chloride of gold stock solution? I have tried one lately published, viz., chloride of gold, 15 grains; acetate of soda, 1 ounce; water, 15 ounces. Also another:—chloride of gold, 15 grains; water, 2 ounces. In the former the gold deposited after a couple of days. The latter kept much longer, but eventually deposited the gold very freely. As I only use an occasional grain I find the stock solutions, as stated, to be very wasteful and disappointing."——In reply: Seeing our correspondent uses so little gold, and at such infrequent intervals, it will be better for him to keep his gold in some other than the stock form mentioned. If it be more convenient to keep the gold in the liquid form, then he must see that it be slightly acid; for, if neutral or alkaline, it will decompose in the manner specified.

Exchange Column.

I will exchange a whole-plate lens (Darlot's) for a half-plate lens.—Address, Studio, Frederick-street, Cardiff.

I will exchange a cottage window and large tree stump, suitable for photographing children. Wanted, large rolling-press.—Address, W. W. Winter, Midland-road, Derby.

I will exchange Dallmeyer's 2c *carte* lens, cost £15 15s.; instantaneous shutter, cost 21s.; another, 8s. 6d. Wanted, Ross's symmetrical lenses, or offers.—Address, T. L. W., 19, Beckenham-road, Penge.

I will exchange a half-plate camera, by Watson, all improvements—three backs, folding tripod, Ross's *carte* lens, and instantaneous shutter—for larger instrument.—Address, X., 7, Abbeygate-terrace, Colchester.

Wanted, a really light and perfect tent for changing plates up to 12 × 10 at least, in exchange for polished opal or flatted crown glass, 12 × 10 bath in mahogany case, or ormolu frames, 12 × 10, by Marion, never opened.—Address, W. Perry, Sandgate.

I will exchange a Lerebour's half-plate portrait lens, in good condition, with stops, for a Dallmeyer's patent wide-angle landscape lens, in good condition, for plates 7½ × 5.—Address, R. S. Bonnallo, 45, Scotholme Villas, Mosley-street, New Basford, Notts.

I will exchange any of the following for useful studio accessories or apparatus, namely, Burr's *carte* lens and camera, nine Victoria lenses, by Darlot, mounted on brass plate, tapestry curtain, with rings complete.—Address, W. Dakin, photographer, Nether-edge, Sheffield.

I will exchange a 10 × 8 camera and portrait lens, reversible, bellows-body, folding tail-board, nearly new; also, magic lantern, three and a-half inch condensers and slides, 10 × 8 dipping-bath; also, Victoria camera, four lenses. Wanted, a half-plate bellows-body camera with good lens, for any of the above, or offers.—Address, T. L. McCann, 49, Greenvale-street, Glasgow.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

Photograph Registered.—

William Butt, Southampton House, East-street, Blandford.—*Photograph of Triplets, Sons and Daughter of Charles W. and Jane Downes, of Blandford.*

W. S. B. S.—Without seeing an example it would be misleading to pass an opinion. Send us one.

E. H. Derham (Boston, U.S.A.).—We shall refer, and perhaps act on your suggestion. Thanks.

Erskine Beveridge.—If you forward a communication here we will transmit it to the gentleman. We cannot give private addresses in this column.

A. E. I.—The market value of the whole is, probably, not more than a couple of pounds. Possibly in the first instance it might have cost ten times the amount.

G. McKay.—We shall possibly have an article on the subject shortly. It would be impossible to give you reliable information in the limited space at our disposal in this column.

C. Clement Leigh.—The advertisement columns of the Journal and Almanac will supply the desired information. We cannot undertake to recommend any particular firm.

W. W.—The best work on retouching with which we are acquainted is that of Messrs. Burrows and Colton. It is now out of print, but you might possibly obtain a copy by advertising.

Wm. Baker.—Most persons have noticed the relief you mention. It will be a matter for you to experiment upon and see if you can secure it when dry. Many would like to know how it is to be accomplished.

Hants.—If you cannot succeed in the light we are now having we do not expect you will get on any better as the summer advances. Bear in mind that the light during the spring is more actinic, as a rule, than at any other period of the year.

Felix.—The lens named will be of too long focus to take a full-length portrait of cabinet size within the length of your studio. You will have to be content with one of shorter focus—say, the next size smaller. The first, however, will be better for half-lengths or busts. If expense be not a serious object with you we should advise your having both.

S. E. J.—The object-glass, though its optical and chemical foci do not coincide, may certainly be employed for the delineation of microscopic objects. All you have to do is to find out the correction necessary (according to the instructions so frequently given in these columns), and you may then rely upon getting satisfactory results—quite as good as if the two foci were coincident.

Hy. Sims.—There is very little doubt that the lens has been injured by the fall, as you say that it does not work so well as formerly. Your best plan is to get some practical optician—the maker of the instrument, if possible—to take the lens out of the dented cell and put it in a new one. When this has been done, in all probability the lens will be restored to its original condition.

A Country Amateur.—The fault in the picture is not in the developing alone, but also in the exposure. The picture is very much over-exposed, and you appear to have had the sun shining into the lens at the time. Cannot you induce some photographic friend to give you a few practical lessons? Seeing half-a-dozen negatives developed will be of more value to you than any amount of reading.

R. J. Bidder.—If you purchased the gelatine as being by the manufacturer named you certainly have been deceived. The sample shows at a glance that it is one of the commonest kinds to be found in the market, and its value is, we should say, not more than tenpence or one shilling per pound—not three-and-sixpence, as you have paid. Such stuff is useless for emulsion work. No wonder you failed.

Lottie.—Many thanks for the promised collection of charming little studies. They certainly will find a conspicuous place in our album. The pictures, if you will permit us to say so, show a very marked improvement on those you first sent, and they were good. Many of the collection are as near perfection as it is possible to obtain in photographs. We shall hope to see some of your work in the next exhibition.

An Experimenter in Carbon.—Why not employ indian-ink in your experiments in tissue-making? It may be somewhat more expensive than lamp black or ivory black, but its colouring power is much greater, consequently it will go further. You can procure it in a moist form, which is a great convenience, as it will save you having to grind it yourself. Any artists' colourman will supply it, as well as any other colours you may require. Use a very soluble gelatine, or you will not succeed.

Norval.—We see no reason why you should not succeed in using dry plates on the West Coast of Africa, provided you adopt the precautions usual for working in hot climates. Of one thing you will have to take especial care, namely, to keep the plates well packed in waterproof or damp-resisting material during the rainy season, otherwise they will be sure to suffer injury. Your safest plan will be to keep the plates in air-tight metal cases, soldered up or otherwise hermetically sealed, to prevent access of moisture, which pervades everything at that season.

Y. E. S.—If you are using the royal arms, and styling yourself "photographer to the Queen," simply because you have executed a few small commissions for Her Majesty, you certainly are rendering yourself liable to a penalty of twenty pounds. Your neighbour, who photographs the prisoners in the county gaol, has no more right to style himself "royal photographer" than you have. Our advice is—take down the arms and drop the title as quickly as possible, or you may find yourself involved in trouble. We believe the authorities intend to enforce this part of the Act rigidly.

Photographic Club.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 4th June, the subject for discussion will be—*The Consideration of the Best Means of Obtaining Density on Gelatine Plates without Resorting to Intensification.* An outdoor meeting will be held on Whit Monday at Welwyn. Train leaves King's Cross at 10.32.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1257. Vol. XXXI.—JUNE 6, 1884.

FREE SILVER AND SENSITIVENESS IN GELATINE EMULSION.

Pursuing the subject of the function performed by free acid in preventing fog in emulsions when an excess of soluble silver salt is present, we may repeat the view we expressed last week, namely, that the action of the acid is simply to retain the organic silver compound in a soluble condition, in which it is removable by washing.

In addition to the instances of similar action quoted in our previous article, we may allude briefly to one or two others which tend to prove that this view is correct. Every dry-plate worker knows what is the result of applying a solution of tannin, gallic acid, or pyrogallol to a film containing free silver. The latter is immediately reduced and the film badly discoloured; but, some years ago, Colonel Stuart Wortley showed that an emulsion plate carrying a large excess of silver together with free acid might be plunged directly into a preservative of the character named without the slightest tendency to the production of fog.

Later, in 1875, Mr. M. Carey Lea described a washed emulsion process, in which the "pellicle," containing a considerable quantity of free silver, was immersed without previous washing in an organifier consisting of various substances, such as tannin, gallic acid, pyro., coffee, and many others, acid being present both in the emulsion and the preservative. Here we have the free silver actually soaked out of the pellicle on a solution of a reducing agent, the reduction being arrested by means of acid. In either of these cases the organifying solution becomes very dark in colour from the formation of an organic silver compound, but retains its clearness because the compound remains in solution.

The presence of an acid during the preparation of an emulsion will thus prevent the formation of an insoluble fog-producing compound; but it will do more than this, as in many cases fog, already present from such causes, may be removed by the action of an acid. Thus, some years ago, we were consulted by a gentleman on the subject of a quantity of washed emulsion which was hopelessly fogged. According to his description of its preparation he had eschewed free silver (not being a believer in the principle) and, consequently, also free acid. Before washing the emulsion it had been tested and found to be all right, but when washed and re-dissolved it was so badly fogged that no trace of an image could be found amongst the general veil.

Upon examination of our friend's formula we found that, in substituting one bromide for another, the difference in combining equivalents had been ignored, and, instead of the emulsion containing a slight excess of soluble bromide, it really carried a large excess of silver and no restraining acid. As a large quantity had been made —involving not only the silver and bromides employed but also the equally-expensive ether and alcohol—it became important, if possible, to utilise the emulsion rather than relegate it to the waste-tub. After one or two experiments we succeeded by dissolving in a concentrated form—adding nitric acid and *rewashing*—in producing an emulsion perfectly free from fog, of good sensitiveness, and only differing from an ordinary one in giving a thinner image. The addition of acid without subsequent washing produced no effect whatever, as the silver compound remained, though in a soluble condition, in which it was easily and entirely removed by washing.

It will be obvious from the tenor of our remarks that we intend to suggest the same application of acids in connection with gelatine emulsion as that we have alluded to in the case of collodion. Assuming the power of utilising the effect of free silver under such circumstances to be an advantage (and reasoning from analogy we see no necessity to doubt it), it seems to us probable that the formation of the gelatino-silver compound which causes the red fog in a gelatine emulsion would be as thoroughly destroyed or arrested in formation as the more definite silver compounds with tannin and similar substances. At the same time there are certain considerations which partially remove gelatine from the exact position occupied by collodion.

First, with regard to the probable advantage to be derived from the use of an excess of silver: we know that prolonged emulsification, increase of temperature, and the addition of an alkali all tend to heighten the sensitiveness of a collodion emulsion in the same manner as in gelatine, but in a less degree. We also know, as has been already stated, that the highest degree of sensitiveness in collodion can only be obtained when the silver is in excess; and it is, therefore, but reasonable to assume that what proves to be the most powerful accelerator with collodion may also be the same with gelatine.

It may be urged that the acid employed will counteract any gain in sensitiveness arising from the excess of silver, because in the ordinary "boiling" process an acid emulsion requires longer cooking; but a moment's consideration will show that the conditions are so obviously changed when free silver is introduced into the question that the objection is not for an instant tenable. That the presence of nitric acid in combination with silver nitrate is not inimical to sensitiveness is proved not only by its action in collodion emulsion, but also in the acid bath introduced in America some years since by Mr. J. W. Black, of Boston. In this an abnormally large proportion of acid was employed, with the result that extreme rapidity and great softness were obtained.

The action of the acid upon the gelatine has, of course, to be taken into account, independently of its suggested fog-preventing power. Thus, we know that if gelatine be heated for a very short time in the presence of an acid, it loses all setting power and becomes converted into a permanently-liquid state. This fact militates against the employment of an excess of acid silver in any of the methods of emulsification which involve the use of the full strength of gelatine during the operation; but, on the other hand, it favours the processes in which precipitation is relied upon.

It does not follow, however, that (bearing in mind the comparatively small quantity of acid necessary and the low temperature usually adopted in the "prolonged emulsification" methods) the effect will be so great as to destroy the setting power of the whole of the gelatine, or even to affect it to a serious extent. If so large a proportion as twenty-five per cent. of the gelatine be destroyed or converted to the soluble salt, it would be removed with the other soluble matters in washing, and, if necessary, could be replaced with fresh after that operation.

But it is in the direction of precipitation that we are inclined to look most hopefully for success—not only as presenting fewer chances of injurious complications arising from the organic silver compound, but also as affording the most convenient and scientific method of preparing a pure emulsion. A minor consideration (one of economy) is to be found in the greater convenience precipitation presents of collecting the surplus silver removed from the emulsion—an important item in the case of large operations.

So far we have said nothing as to the practical results to be obtained when working on these lines. We have preferred just to give in detail the principles upon which we have proceeded, and shall shortly publish the results of a number of experiments in the direction indicated.

CERTAIN NICETIES IN FOCUSSING.

When recently attempting to focus a subject of extreme delicacy we found the ground glass of the camera much too coarse for the purpose, notwithstanding the fact of its being a specimen of the finest ground glass possible to be obtained. This is an experience, we may observe, that is more or less common to all who attempt to photograph diatoms and microscopic objects of the finer class. The point of best focus can readily be ascertained, more especially if recourse be had to the magnifying services of a focussing eyepiece of low power. But the amount or extent of the definition cannot always be perceived; for, when to secure this end the power of the eyepiece is increased, then the granulated surface of the focussing-screen appears so coarse as to prevent the desired end from being attained.

It is all very well to tell us to discard a ground surface in favour of a plate of plain glass; but this presupposes the function of the focussing-screen to be limited to that purpose from which it derives its appellation, namely, that of focussing upon, whereas one important use of this surface is to permit of the composition of the subject being properly noted and arranged.

The highest order of focussing is that effected by the aid of a compound microscope, by which we here mean two *systems* of lenses in a focussing eyepiece instead of one. To explain: a direct magnifier—composed usually of one, but sometimes of two, or even more, lenses—represents the latter, and by means of it the image on the ground glass is itself viewed; but by the former we mean such a system as that by which a second or virtual image of that which is on the focussing-screen is formed at the other side of a lens, and which image is viewed by a second or eyepiece system. This forms the best of all focussing-tubes, because it may be easily made in such a manner as that, when once adjusted to the front surface of the focussing-screen, a difference so trifling as the ten-thousandth part of an inch in racking in or out the photographic objective can be readily perceived from the degree of sharpness of the image. This is, of course, assuming a very careful measure of correction of the photographic lens.

Desirous of "running to earth" this subject of focussing, we first of all constructed a compound focussing eyepiece. It consisted externally of a paper tube, formed by wrapping a long strip of *The Times* newspaper, six inches in width, round a circular desk ruler with a cement of ordinary glue, made rather thin, between each layer. When the glue was dried the rigidity of this tube was marvellous.

Just here, and while on this subject, let us say a few words on paper tubes. In our estimation paste, which has so commonly been recommended as the means of uniting firmly together layers of paper, is greatly inferior to glue. We speak of this after acquiring some experience in the formation of two or three long tubes for astronomical telescopes. Let any reader make one tube, long or short, of a few thicknesses of brown paper well saturated with flour paste, and a second tube in which glue forms the cement, and he will be satisfied as to which is the better. One of the latter, about four feet in length and three and three-quarter inches diameter, which we had placed on the roof of a house to dry, was caught (after being dried) by a gust of wind, and after being carried more than sixty feet was thrown against a hard pavement without sustaining the slightest damage.

Into a tube formed of this material we inserted a cheap, French-made one-and-a-half-inch microscopic power of the usual triplet class, inserting at the other end an ocular composed of two plano-convex crown-glass lenses, mounted Huyghenian eyepiece fashion. By the aid of a cap sliding over the tube we adjusted this compound focussing system so that when the lower end of the tube was pressed in contact with the back of the focussing-screen the granulated surface of the other side of the glass was in sharp focus. By means of delicate scratches made on the anterior surface of the plain glass, intended as a substitute for the ground glass, we found that the thickness of both was identical.

Here, now, became apparent a difficulty that had been to some extent anticipated. When focussing upon the plain glass we could obtain, without any difficulty, a focus which was absolutely sharp. It only sufficed to place the end of the pocket compound focussing microscope, just described, firmly against the focussing-screen and rack the lens in or out until the maximum visual sharpness was obtained, precisely in the manner in which a telescope is used, and upon a sensitive plate then inserted was found delineated all the sharpness of definition which the lens employed was capable of yielding. This was all right, so far as it went; but upon a plain plate of glass it was found to be wellnigh impossible to adjust the subject as a composition. On the other hand, when the ground-glass screen was employed it was found to be difficult to focus sharply.

After some consideration we formed a circular hole in the centre of the ground glass by making a perforation, half-an-inch in diameter, as nearly in the centre as possible. This we did by chucking a small piece of brass tube in the turning lathe and applying emery powder and water to the end, pressing this against the plate of glass, by which a hole was speedily cut through. To this hole the microscope was applied after making a very slight adjustment to compensate for the removal of the thickness of the glass and restore the equilibrium of spherical correction.

This system worked to perfection; but we reflected that, from a practical, everyday point of view, it would be preposterous to expect photographers to be able to "follow suit," as the number who have appliances for effecting the perforation of the ground glass is necessarily limited. We therefore tried the effect of polishing a small portion of the centre of the ground glass. This experiment, too, was attended with success; but, like the one previously described, it was troublesome.

We eventually hit upon the thing of all others best adapted to the purpose, and we can recommend it as costing comparatively nothing either in expenditure of cash or trouble, while it fulfils the purpose desired in a satisfactory manner. It is as follows:—

Having rendered the ground-glass surface of the focussing-screen quite clean, take one of the circular thin glasses employed for covering the objects on microscopic slides, which are sold by all opticians for this purpose at so much an ounce, and having placed a small drop of Canada balsam upon the centre apply it to the ground surface of the focussing-screen as near to the middle as possible. Instantly the granulated surface disappears (at least sufficiently so for our purpose) in favour of a bright, polished spot. By the application of heat the small portion of balsam that oozes out at the margins of the disc of microscopic glass—which may vary in diameter from half-an-inch to three-quarters or more—soon becomes sufficiently hardened to enable it to be chipped away by the point of a knife, or dissolved by the application of benzole or ether.

Next week we shall take occasion to follow up certain ideas here indicated.

EOSINE IN THE COLLODION PROCESS.

Everyone knows the difficulties attendant upon, and the unsatisfactory results which, as a rule, are obtained in copying works of art. The real difficulty is that of rendering in monochrome by photography the different colours of the picture in their correct value. It frequently happens that the lights and shades in certain portions of a painting are completely reversed in the photograph, if the former contain a large proportion of yellow and the latter blue or violet. This, of course, often renders the photographic copy little short of a burlesque on the original.

On the continent, where the reproduction of works of art is made a greater feature as a branch of business than in this country, much better results are usually obtained. We have in our mind's eye just now some of the wonderful reproductions from the old masters by MM. Braun, of Dornach, MM. Goupil's reproductions by their *photogravure* process, and the works of other firms we could mention. It is not our present intention to refer to the causes frequently assigned for this superiority, as allusions have been made to them in our columns on previous occasions. It may, however, be remembered that, a year or so since, a report gained currency that the superiority of the work issued by some of the continental firms was due to the employment of a modified collodion process, by which the colours of the picture were rendered in the photograph in the same relation as to tone as occurred in the painting. About the same time MM. Clayton and Tailfer, of Paris, introduced a special make of gelatine plates, for which it is claimed that they reproduce colours in their correct relation, this being secured, it is said, by the introduction of eosine—one of the aniline dyes—into the emulsion. These plates are now, we believe, an article of commerce in France, though, so far as we are aware, they have not been introduced into this country, consequently we have had no opportunity of testing their merits.

Recently, Dr. Vogel has brought the subject of rendering colours in their true proportion by photography before the Berlin Association for the Cultivation of Photography, and described a means by which he claims that the collodion film is rendered *eight times more sensitive to the yellow than to the blue rays.* This result is obtained by the addition to a bromised collodion, containing a little iodide, of a certain proportion of eosine. The after operations of developing, intensifying, and fixing the negative are much the same as those of the ordinary wet collodion process, similar solutions being used ; so it will at once be seen that the new process is by no means beset with complications.

The idea of employing different colouring matters in the sensitive film, with the view of absorbing the more non-actinic rays, is by no means a new one, as it was promulgated several years ago, and at different periods many have tried it, but with varied results. Some experimentalists have maintained that certain advantages were gained by the addition ; while others, on the contrary, affirmed that no advantage whatever accrued, and, furthermore, gave reasons why none should be expected.

Up to the present time, so far as we know, the plan has never been brought into use commercially, unless, indeed, it has been worked as a "secret process." It is quite possible, after all, that the discrepancies in the results hitherto obtained by different experimentalists may, in a measure, be due to the particular method of working adopted by them or to the character of the colouring material employed. Be that as it may, Dr. Vogel, who has devoted considerable attention to the subject for many years past, has now published in the *Mittheilungen* full working details of his process, which we reproduce [see page 244 *ante*, and page 360 of the current issue], so that any one may try it, and on its merits decide for himself.

Presuming the process will accomplish or secure even a portion of what is claimed for it by Dr. Vogel, it is simply impossible to overrate its value to those who make a speciality of copying works of art; because, however skillfully a negative may be retouched or the painting itself may be manipulated or "dodged," the copy can never possess the same value it would have done if equal results could be obtained direct from the original without sophistication. Whatever advantages may be obtained by the new process we can foresee they will not be gained without some attendant inconveniences, and of these Dr. Vogel appears to be fully cognisant.

For example : we are told that the eosine-bromised plates are about three times slower to white light than ordinary wet collodion plates; and, further, it is advised, in the event of blues coming out too light in spite of the eosine, to take the negative through a plate of yellow glass, which, as a matter of course, will still further prolong the exposure. When we consider that in copying oil paintings it is generally necessary to stop off a large proportion of the light falling upon them in order to avoid reflections, it will be seen that the exposure will become inconveniently long. Furthermore : when large sizes have to be produced—say on plates of twenty-five or thirty inches, such as those produced by some of the continental houses—lenses of long foci become imperative, and even then very small stops must be used in order to obtain good definition over the large plate ; hence, it will be observed, a very long exposure will be absolutely necessary in working this process. We are aware it is no uncommon thing for an exposure of three-quarters of an hour or longer to be given in the ordinary wet collodion process, as at present employed, when copying old oil paintings. Occasionally, when a painting cannot be removed (as is the case in some collections) and it has to be copied *in situ*, several hours' exposure is frequently necessary. In such cases the new process will, of course, be placed at a considerable disadvantage.

Now, the great difficulty in working the wet collodion process with such protracted exposures is that of preventing the plate from drying, or partially drying, during the time. To overcome this Dr. Vogel employs a dark slide with a plate-glass front, so that the evaporation is to a great extent retarded. It appears, also, that the eosine has a very injurious action upon the silver bath, which causes it to become disordered after a few plates have been sensitised ; indeed, two baths appear to be necessary in practice—the second to immerse the plate in prior to development, so as to remove the impurity left by the first. However, this is a very trifling matter, as large plates are usually sensitised in horizontal baths, so that only sufficient solution to cover the plate need be used. When this becomes disordered it can be discarded and a new one taken into use. The old solution can then be restored at leisure in the ordinary way, or added to the residues, without incurring much trouble if the former plan be adopted, or much loss if the latter be employed.

These comparatively trivial inconveniences, however, are scarcely worthy of consideration if the results to be obtained approximate to what is claimed for the process. They certainly are not of such a character as to deter for a moment any person from giving the process a fair trial now that such full and complete working details are published, particularly when we consider that it is quite possible, as the result of further experience, that the difficulties to which we have alluded may be eventually overcome, or at least considerably ameliorated.

If the value claimed for eosine in collodion can be secured equally well in the gelatine process it will prove an immense advantage, as then the difficulties of disordered baths and protracted exposures will be entirely obviated. We are pleased to learn that Dr. Vogel is still experimenting in this direction, and we hope he will be able to bring his experiments to a successful issue.

OPACITY OF FILM AND QUALITY OF IMAGE.

In the search for sensitiveness in gelatine plates almost all other qualities were for a long time ignored ; so long as a plate was extremely sensitive, and especially if it did not frill, it was looked upon as pre-eminent, though, certainly, we may say density was, almost concurrently, considered a desirable characteristic, but it held quite a second place. Quality of image was about the last thing sought for, and, indeed, at the present day it is only occasionally that, irrespective of the question of density and clearness of the shadows, it has been discussed to any serious extent.

We have for some time past been making a series of trials of various makes of plates with this particular point in view, and we have formed a very positive impression as to the bearing of facts in, at anyrate, one direction. The distinct opinion we have arrived at is that, outside all considerations of iodide or chloride admixture with the gelatino-bromide, the opacity of the film exercises a most important part in determining the character of the image. The addition of iodide has been said to make a plate less sensitive, and also to increase its sensitiveness—to render it more and to render it less liable to green fog, more sensitive to the red, and less sensitive ; in fact, to perform all the most contradictory feats imaginable. But that this greater or less opacity of the film, especially in portraiture, affects the character of the image as regards delicacy, crispness, and range of tone may be conclusively proved. The facts upon which this effect is based are well known; it is their application upon which we would lay stress and draw attention, seeing that, so far as we have observed, little or no publicity has hitherto been given to any such opinion.

A very little argument will prove our position, and, if we mistake not, indicate a point of departure for all dry-plate-making experiments. "A good, thick film" has for some time been looked upon as a *desideratum* without any very logical reason being assigned. We proceed to indicate our views as to its function. There has not been an exhibition in Pall Mall yet in which the presence of "halation" has not marred some of the pictures hung. Parts that should have been black have been in some instances so affected as not to be deeper than a middle tint—sometimes to the ruin of a picture, and at others scarcely to the injury of the effect at all; but if a plate be liable at all to halation, little or much, who can say when the effect will not be most prominent and most injurious? If anyone look through an album of portraits by different artists he will find in almost one-half of them, where a white collar and a black coat are portrayed, that the purity of the deep black is degraded close to the collar owing to halation; while in cases where much linen is displayed the effect is sometimes ludicrous, a species of aureole surrounding the dignity of a large white cuff or the weeds of a widow displayed over her sombre attire.

We have before us two pictures, in taking which similar difficulties met the operator, but which have been encountered very differently—one being a steamship taken by a photographer in the north, and the other a large crane by an artist in the south. In each case there were fine lines of dark ropes or chains set upon a background of clouds—a most difficult class of subject. In the first named they were as sharply rendered as though cut out of the negative with a knife; in the second they were grey and flat to a degree.

Now, without any knowledge of the mode of manipulation employed, we have little hesitation in saying that the one was taken with an opaque film and the other with a more translucent one. So far the inference from these facts would not be disputed, but we will go a step further. We would ask—Can it be doubted that, if a gross amount of degradation of shadows can be indubitably shown in some cases, there are a multitude of others where the lighter tones must also be degraded, but in a manner that cannot be readily seen and pointed out? It is the absence of this degradation that causes the effects termed "crispness," "pluck," "brilliancy," &c., and it is its presence that reduces the variety of tones by merging the more delicate ones into the high lights, so as to cause complete absence of tone.

When the light on a plate is very feeble, either through slight illumination of the view or portrait, or through excessive stopping down, halation is reduced to a minimum or is entirely absent. In such cases a thin film is equal to a thick one. But when the subject is brightly illuminated, or a large diaphragm is employed, those parts of the plate which receive a bright portion of the image allow it to pass through and become reflected in the now well-known manner. Similarly with a portrait. With average illumination and a stop not too small a thin plate will allow sufficient light to pass through that portion where the image of the face is thrown to be reflected back to the film, and so destroy those delicate tones that lend such beauty to a photograph. But, as when the light is poor (which is so often the case in our variable climate) or a diaphragm is used, the light becomes too much reduced to have much effect, this special characteristic is lost sight of, and the distinct defect of a thin plate remains undetected.

It is very difficult to point out—as can be so easily done in the case of a white cuff, or an open book on a black surface, &c.—an example of this defect in the lighter parts of the picture; but we can show how it may be easily appreciated. Let anyone take two or three negatives on thin and two or three on thick films of a lady in a white dress, or of a chorister, for example, in his white gown, choosing a bright light, using no diaphragm, and not "backing" either of the kinds of plates. Let him obtain the best negative he can, and he will find that the thick film gives an infinitely better effect than the thin, no matter what developer he employs.

This will be further seen on the back of the plate. The thin film will exhibit the whole of the image at the back, while the thicker film will show less of the image, or none at all, according to the amount of its opacity. There will, however, be more to be observed than this. The image seen at the back of the thin film will have a misty, unsharp, or fogged appearance, while that slightly showing through a thicker film will be crisp and sharp—the first instance being distinctly a localised fogging of the image in special portions only.

It will thus be seen that the old criterion of the correctness of the exposure, namely, the image showing through to the back, will be quite useless for some plates—plates that we would recommend—and could only be of service in the thinner and more defective plates.

We need not point out that a great deal of this effect of halation proper and of degradation of the middle tints will be greatly diminished by the use of backing. They will not be entirely diminished, but all such additional labour should be avoided, if possible; and this will be facilitated by the use of a plate with a thick film. Such a class of plates entails other difficulties which we cannot now discuss; but we may say that the greater the number of plates we have experimented with in this direction the stronger grows upon us the conviction of the great superiority of an opaque film—so much so that we hazard the opinion that in half-a-dozen years' time, for ordinary work, it will beat all other (thin) plates out of the market.

There exists a pretty close intimacy, as a rule, between the theatrical and photographic professions, but it is perhaps impossible to expect that they should always rub on together with perfect smoothness. Here, at least, is evidence that somebody (the photographer, of course) has been "had" once, and doesn't mean to allow it again. The correspondence reaches us from a midland town:—

Says the "acting manager" of a travelling company:—"Dear sir,—Do you make any charge to the dramatic profession for photos.? I require some for professional use only, and have heard you very highly spoken of. Should be glad if you would drop me a line," &c., &c.

In response to this the guileless collodion man says:—"In reply to your note received this day I beg to say that when the places of dramatic entertainment are thrown open free of charge to the photographic profession, then you will probably be able to obtain what photographs you may require without paying for them. Until such somewhat doubtful advantage is attained I, for your further information, beg to say that my terms are—for *cartes*, 6s. per dozen; for cabinets, 12s. per dozen; and *with the profession strictly cash with order*.—I am, yours," &c.

We have employed the italics because we think that this photographer's knowledge of "the profession" deserves emphasising. If some of the "guinea-a-dozen" *carte* men would do less in the way of *not* making "any charge to the dramatic profession," many of their fellows in, perhaps, a less flourishing way of business would be saved a great deal of trouble from such attempts as the above, usually made by the "tag-rag and bob-tail" of the profession they do anything but adorn.

We read about a new patent cork lately invented, to be called the "reversible distributor cork," which seems to possess promise of usefulness. It is coned from the middle to each end so as to fit either way up, and, in addition, has at one end a pair of grooves cut opposite one another, starting at the middle and terminating at the extremity, so as to enable the ubiquitous "drop" to be delivered—one groove permitting the fluid to pass while the other admits the necessary amount of air.

By the way, why are not all corks made cone-shape, or "taper," as the technical term runs? If we send to the nearest chemist for a dozen or two corks we are too apt to be supplied with a number of short rods instead of a nice cone-shaped, elastic stopper of beautiful velvety-looking material—as different from the "cork" rods as a building brick is from a majolica vase. We learn, too, that the term "velvet" also is appropriated by the cork-cutters to describe one superfine quality of material. We shall in future always ask for "velvet taper corks" when we require an easy-fitting stopper that will neither send a dust spray into the bottle to which it is applied nor break off short when we attempt to extract it.

Last week we alluded to the new substitute for bichromate of potash—the bichromate of soda—which it was advertised by the makers would be much cheaper than the older salt. It would, however, need to be vended at a very low rate if it is to successfully compete with the potash salt spoken of at the meeting of the Applied Chemistry Section of the Society of Arts on the 28th ult. Mr. Barr, the maker of an ingenious primary battery, said that when his firm commenced the manufacture of the batteries they paid sevenpence per pound for bichromate of potash, while now they only gave threepence halfpenny for it. It occurs to us that possibly it is the soda salt that he referred to when quoting the lower price.

The old familiar sulphate of iron, usually shortened to "iron" among photographers, is recently exhibited in quite a new *rôle*, a chemical investigator having ascertained that it possesses high manurial value, while he now informs us that chlorophyll—that marvellous colouring matter which furnishes the prevailing tint of green that beautifies the face of the globe, or would do if we had a little more rain—owes also its colour to sulphate of iron. He considers it probable that in "the chlorophyll cells the molecules of ferrous sulphate which are taken up by the roots are constantly being decomposed, the iron combining with the colourless variety of this glucoside (that is, the *leukoplastids* of the vegetable physiologist) forming the green glucoside (chlorophyll)." It will be singular if the colour which of all others is most antagonistic to the action of the developing solution should really turn out to be caused by the main constituent of that solution.

It will be remembered that about a year or two ago the scientific papers were full of accounts of a new mode of preparing aluminium, which, it was asserted, would cause its price to be so low as to bring it into common use. Nothing further was heard of the process, and in Messrs. Spon's new *Workshop Receipts* reference is made to the method, which, it is stated, only cheapens the price of alumina, not the metal. This book states that if the method enabled the alumina to be produced even fifty per cent. cheaper than by that of a well-known maker on the continent it would only cheapen the price of the metal five per cent.

The example set by Oxford and Cambridge in declining to exclude the fairer portion of the community is becoming contagious. The other day the Royal Microscopical Society held solemn conclave to decide whether they should admit ladies to the privileges of the Society, and they passed a resolution—"That ladies shall be eligible as Fellows of the Society, and shall be subject to all the obligations and entitled to all the privileges of Fellows, except that they shall not be entitled to attend the ordinary meetings of the Society." We think that lady photographers would, if we may be allowed the expression, be received with open arms by the leading photographic societies of the country.

In connection with the old silver print and its singular set-off on the backboard of the frame that held it that we described in our last issue, we have been able to ascertain how it was produced. The plain paper was coated with a solution founded on the lines of a formula published by our late esteemed *collaborateur*, Mr. Thomas Sutton, and was as follows:—

Chloride of sodium	10 grains.
Gelatine	1 grain.
Sugar of milk	30 grains.
Distilled water	1 ounce.

It was toned, we learn, by *sel d'or*, and is, as we said, a beautiful colour. Seeing that it was, as we are informed, printed from a "converted positive," as the term run in those days, there never could have been much half-tone in it; hence it is practically as good now as upon the day it was first produced, though it has been knocking about without any care whatever having been given to it.

COLOURED AND NON-ACTINIC LIGHT.

In reply to Mr W. E. Debenham's article: I think if he refer to mine again he will see that I did take account of the different illuminating powers of different parts of the spectrum, and that the greater portion of my remarks towards the end was in the express direction of his own question—"Which part of the spectrum possesses the least effect upon the photographic film *in proportion to its illuminating power?*" Looking over what I wrote, I really seem (to myself) to have gone very directly to that precise point, though I know "the heart is deceitful above all things" in matters of one's own authorship. Mr. Debenham "has" me fairly enough in another matter, for the simple reason that I made no attempt to treat exhaustively of the subject, and would, indeed, have thought it presumptuous to attempt more than some main outlines. He is, for instance, quite right in saying that some media which pass little visible light may pass *invisible* actinic rays. But, practically, this objection applies to scarcely any media likely to be used in experiment; and hence I took no notice of a point which perhaps ought not to have been omitted. In practice it will be rather difficult to find a medium which only passes the less actinic of the visible rays, that does much harm by invisible rays, and so I let it alone.

There will not be much difference between us if I say that in my remarks I made not so much reference to the final and conclusive results, as to which I concur that the photographic plate must be the final appeal, as to the preliminary work of choosing and compounding media. The prism, *merely used at the eye*, does swiftly and surely what otherwise is haphazard; and it is most of all advantageous *because* most media "allow more than one band to pass." Taking any two, three, or four media, one glance through the prism shows at once the residual light which gets through the whole; and, since the eye itself can judge of the visual effect, the operator knows at once if he has got a *promising* combination, which can then be submitted to more crucial tests. But the prism infallibly casts out at once, without further trouble, media or combinations which cannot possibly lead to any good result, though they might consume much time and many plates if tried on account of their appearance to the eye alone.

So, again, my remarks as to differences in plates referred to the case of absolutely "non-actinic" light. If such do exist at all, my remark was that it could be only for one precise condition of the salt. In practice, on the other hand, I referred to "a wide range of bromide plates" as showing broadly the same result.

About the effect of exposure on sensitiveness I can pretend to no authority; but my impression was founded on *many* scattered statements here and there. It must be borne in mind that all plates do have some exposure. Query: would a bromide-gelatine plate prepared from first to last in *absolute* darkness be as sensitive as one prepared in the usual way? My impression, gathered mainly from facts I have seen stated, is that it would not be. Mr. Debenham thinks it would be. The question is exceedingly interesting from the molecular point of view; and I should think it was of enough practical importance to be decided beyond cavil. Meantime dogmatism on either side is probably unwise.

The question in the last paragraph of the article is a very simple one—another of those which is at once answered by the prism; and here let me say that when I mention the prism I mean no complicated "spectroscope," but simply a prism of any kind, *held at the eye*, though a direct vision is the best, and a small thirty-shilling pocket spectroscope handier still. Nearly all coloured media transmit more than one colour, as Mr. Debenham has noted, and most of them show more than one absorption band. Now, by using more and more of the medium it will be seen that the bands become wider and darker, till at last two bands may approach and coalesce. There is no better example than the litmus solution so often mentioned in text-books. Suppose we have it in a wedge-shaped cell, so that we can look through gradually-increasing quantities. A thin layer only shows a narrow band near the D lines. As we pass the observation-slit towards the thick end of the cell this band rapidly widens and darkens, and another appears at the violet end; and as more medium is employed these bands approach till there is perceptible absorption even midway, and the total light allowed to pass is a purplish-red instead of blue. The explanation, of course, is that there really is *some* absorption in the thinnest layer long before the eye can take account of it. As we add more medium *all* the absorptions increase, but not all in the same ratio; so that the final colour may be very different from the first. The prism will show beautifully how successive portions of the spectrum are gradually encroached upon by more of the absorbing material, till at last total obscuration is the result. The glass coloured with copper oxide changes little or nothing except towards darkness, because at the very first most samples transmit only reddish rays. But as half the whole spectrum at the red end, when gathered together, appears orange, or even yellow *if more green be taken in*, and the other whole half appears blue, it is easy to see what changes may be made by greater and greater absorptions in blue or yellow of such a compound nature, instantly revealed by the prism, though the eye is deceived.

I was rather interested, and may frankly say puzzled, by the alleged effect of passing light through a *diffraction grating*, as mentioned at a meeting of the London and Provincial Photographic Association. That employed would probably be a photographic copy of Nobert's; and the usual size (about one and one-eighth of an inch square, 3,000 lines to the inch) I have seen advertised in the *English Mechanic* at half-a-guinea. Mr. Lettsom's, which was referred to, if a Rutherfurd (which it probably is), would be on speculum metal, and would give reflected spectra, with, probably, different results. Professor Rowland's are also on speculum metal, and one four inches square costs from £8 to £12; smaller ones are much cheaper. Mr. Brashear, who has the disposal of them, informs me that they are not at present ruled upon glass, as the demand for metal ones cannot be supplied. These are far the best yet made, when the best quality is obtained.

Another expedient may be worth investigation. As Mr. Darker observed, there are many methods of modifying light; and there *might* be photographic advantages in passing light through *fluorescent* media. The rays most active in exciting fluorescence are the *most actinic* also, and in doing this work they are bound to disappear. Two or three layers on glass of even luminous paint must necessarily absorb most of the *invisible* actinic rays, for instance, though the visible rays may remain. But a cell of eosine solution might be worth trying, and so might a piece of uranium glass in combination with other media. Probably neither would answer alone; but most of these substances are such powerful absorbents of all the *invisible* actinic rays that in combination they should be useful, and both the yellowish-green of the uranium glass and the orange-red of the eosine would not be bad colours to start with as the foundation. Has anyone ever tried the two in combination? The glass can be got in small pieces of sheet very readily. LEWIS WRIGHT

P.S.—By a strange coincidence, since the above was despatched on Monday, I have had the pleasure of seeing the solar spectrum as shown by Mr. Lettsom's magnificent grating, in company with Mr. Darker. It is, as I supposed, a Rutherfurd, on speculum metal.—L. W.

CLOUD PHOTOGRAPHY.

OF all the classes of subjects which are presented to the camera that of clouds receives but little attention. Whether it is because these lovely objects are common to every place alike (too common in England sometimes, perhaps) that none are worth pictorial record, or that there are not the opportunities as in landscape work for the display of taste and skill, is not evident. There is a failure, at anyrate, of one great incentive, in that a picture composed principally of cloud would not excite the pleasurable sensations derived from old associations and enjoyment as one of a place visited; therefore, the impulse to practice this branch of photography must arise more from the love of depicting the beautiful. With the dictum that one needs but little skill I most certainly disagree.

The chief charm of cloudland consists in the great variety and ever-changeableness of its character. When a grand effect displays itself it is on this account of more importance to secure a photograph, and because of the certainty of its never recurring. There may be similar ones of the same class, and although the likeness may be great there is still variety.

Cloud photography up to the present, except in a few instances, has been limited to the production of those of a marked character, for the purpose of breaking up bad skies in landscapes. As for this purpose it is necessary that they be thin in the negative and quick printers, to suit the requirements of double printing, and also not too obtrusive when appearing over a landscape where breadth and depth of tints are so small that anything beyond a mere indication would detract instead of enhance, all their beauty excepting that of form is suppressed, and the loveliness of their delicate gradation is never seen. Now, negatives of clouds for pictures in which the landscape is to be subordinated must have their scale of gradation complete, and therefore require, in comparison with the thin ones mentioned above, rather longer printing.

In these cases the process of double-printing should be reversed, the cloud being first printed to a depth sufficient for its finer details to escape the destroying influence of the toning and fixing baths, and the landscape printed up to harmonise with it. This procedure is absolutely necessary. The great difficulty is to obtain brilliancy. The lights of nature are so pure and strong, and the extremes of light and dark so great, that the artist is compelled to resort to opposition of extremes and juxtaposition of colours to eliminate the muddy element from his comparatively-restricted scale of tints, which range from dirty grey to black. Nothing on paper or in pigment will bear placing beside nature, for lack of purity pervades all that is artificial. The nearest approach to natural effects in respect of brilliancy would be found in transparencies illuminated by electricity. These being the most perfect kind of photographs, in not having the greater part of their details washed out or clogged as in paper photography, the richness and depth of shadows could be made to subdue the strong illumination, while its full power sparkled through the highest lights. Paper work alongside is crude and out of the hunt. I never have seen a good cloud on a paper photograph; they invariably fail to show all gradations of tone. The art has yet to be mastered; the process is still wanting.

The skill and judgment required to successfully photograph the beauties of the sky are of a very high order. Some of these, however—such as the masses of cumulus in a storm-cleared sky—are not very difficult; and upon these it would be well for a new adventurer in the field to commence. In their being strongly contrasted with the blue background the duration of exposure and after treatment of the plate need no special care. It is otherwise when delicate cirrus, "mares' tails," "mackerel" skies, masses of cumulus in heat haze, storm clouds, and evening effects are attempted. These tax one's ingenuity to the utmost. The very slight difference in the photographic action of the various parts render it necessary to use the greatest care in timing the exposure and restraining development to intensify this slight difference as much as possible; otherwise a plate simply exposed to light and developed will give an equal and possibly a superior result.

Evening skies are most deceptive on account of colour. It is not advisable to attempt these too late. Some of the brilliant effects appearing a short time before sundown, in the absence of haze, photograph easily; whilst others fail to impress anything besides a few of their main features. I was on one occasion most thoroughly deceived in an evening sky. It was a very fine one—all aglow in colour, with just sufficient haze to allow one to define the sun's limb without distressing the eyes. Two plates were exposed, with no other result than that of impressing the contours of a few of the upper clouds, the sum of those near the horizon consisting in a slight and uniform fog—no sun, nothing beside. It was rather expected that the orb would have given some slight indication of his presence, but not the faintest trace of him was visible. He, in common, and equally with his surroundings, had contributed sufficient light to produce fog, neither more nor less.

If the design in photographing clouds were for pictorial purposes only many of the most difficult kinds need never be attempted. Should, however, the photographs be required for scientific use in meteorology, then all kinds of these valuable weather signs must of necessity be obtained, partial record being of little, if any, use. The camera must be out in almost all states of wind and weather, when uniformity of tint does not prevail.

The best selection of clouds for general professional work are those appearing after a sou'-wester or during the prevalence of a westerly wind. Absence of haze is the distinguishing characteristic of weather from this quarter; whereas those appearing in the N.E. (here at Littlehampton, at anyrate) are pea-soupy, mangy, plague-striken-looking things poisoned, I firmly believe, with "London particular;" for yellow haze is perceptible a few hours after a change of wind into this quarter, and in winter especially this smoky veil hangs over us like a very dirty yellow blanket. It is our "plague wind"—a curse to photography and photographers. Half a gale from the S.W. is heralded with unmixed feelings.

To enable pictures to be made at all points of the compass an elevated position or an open space is, of course, a necessity. The camera should be of a substantial make, light-tight in strong light, and fitted with a hood in front to cut off all extraneous and useless light. A view meter or sights is an important addition. Its stand must be firm and strong—to attain which leave the element of portability out—and its head fitted with a means for moving it in a vertical direction and in a horizontal circular one. A ball-and-socket motion is the kind of thing, if it were not spoiled by tendency to vibration in high winds. Whatever arrangement is adopted its adjustments must be free and firm, for no time can be spared in dealing with quickly-moving clouds; they will very soon pass into the wrong place on the plate. Focussing having been once performed for clouds with a particular lens, the camera may be marked and the screen removed.

The single lens is the best adapted for use, from its being more brilliant in action and free from the annoying reflections which arise when double combinations are presented sunward, or to other intensely-illuminated spots. In the use of the stop attention should be paid to the fact that the smaller the one used the lesser the brilliancy, and *vice versâ;* therefore, with subjects deficient in contrast, enlarge the aperture and reduce the exposure. This is a matter of great importance, and frequently makes all the difference between success and failure.

Let the rapid shutter be an adjustable one, with a range from about one-hundredth of a second, or less, to a second and a-half. It will be gathered from what has been already written that the great stumbling-block in this branch, as in all photography, is the judging of the exposure, the difficulty, however, being much increased from the fact that its latitude is more restricted, the interval of time being shorter; that intervening between under- and over-exposure of a mackerel sky would be but a small fraction of a second.

In selecting the kind of plate, that capable of yielding the greatest scale of tints in their true relation, together with freedom from fog and cloudiness, are the qualities to be taken note of. It need not be of a very rapid description. Their coating should be liberal and opaque, or they must be backed with a solution of asphaltum in benzole, for halation is not required. Be sure of its working clean. Rapidity may be sacrificed, and with advantage, to ensure this. Development must be well restrained and cautious, and rather inclining to excess of vigour till sufficient progress is made to enable an exact judgment to be formed as to what treatment it must receive. Wet plates are preferable to gelatine ones. They are quite rapid enough, and well under control; but one might just as well speak of daguerreotype and waxed paper as make any remark in favour of wet collodion.

Nothing need be said respecting fixing, this operation being as usual. Should the negative, however, require much intensification, and of a fine effect too good to throw away, intensify it to full strength and reproduce it by carbon transparency. The fog and thickness may be eliminated in the process and a fair result obtained. Bear in mind the purpose for which the clouds are intended. If for printing-in purposes they must be kept thin and clear; if for cloud pictures they should be fairly intense and full of detail.

The negatives in possession, their printing into landscapes is an easy matter. About the simplest plan to follow is to take the printed landscape and tear out a piece of paper to the shape of its sky line, adjust the print upon the cloud negative, close the frame, and take it out to print in the sun, during which keep the mask gently moving to prevent abrupt lines, but with care not to fog the edges of the landscape. Tear the paper slightly larger than those parts projecting into the sky, so that the chances of their being exposed may be as small as possible. As one does not approve of this operation taking up much time, the negatives are made thin and clear, so that a few seconds may suffice. In selecting a cloud for a picture, while the question of pictorial suitability is receiving full attention, some thought should be expended in making choice of such as have deep portions to shelter any projecting parts whose purity would be spoiled by exposure to light. To illustrate: a tower or spire or any other object might appear in a light portion of cloud, and be thus protected—to the advantage of the picture, in all probability, in its pictorial aspect. JOHN HARMER.

ON THE DEVELOPMENT OF INSTANTANEOUS PICTURES.

[A communication to the Liverpool Amateur Photographic Association.]

WHEN, somewhat rashly perhaps, I ventured at last month's meeting upon adding a few words to the discussion upon the development of instantaneous negatives, I did not anticipate that the penalty would be that I should be put into the forefront of the battle tonight. Had I done so I might probably have considered discretion to be the better part of valour. Yet, as I think it the duty of every member of a Society like this to contribute what he can to the general benefit, even though it be but the widow's mite, I could not refuse to obey the call, although I am conscious that I shall contribute nothing new and nothing probably which other members of the Society would not be better able to bring before you.

Mr. R. Crowe, in his interesting remarks upon the subject last month, divided instantaneous negatives (by which I presume are meant those taken by the aid of a quick-acting shutter) into three classes. Now, I accept his principle, so far as believing that all instantaneous negatives are by no means to be treated alike; but would prefer to make *two* divisions only, namely, fully-exposed and under-exposed negatives. There is one class of instantaneous negatives which, requiring only a very brief exposure, have by means of the shutter received quite as much as they need. Such are sea views, which I look upon as instantaneous pictures merely in name—that is to say, they are as fully exposed by action of the light lasting only a fraction of a second as the average of plates where there is nothing to limit the amount of exposure but the photographer's own judgment.

In Mr. W. K. Burton's table of exposures I note that, for a view containing open sea and sky in good light, the correct exposure with a lens of $\frac{f}{8}$ (about the aperture of the No. 1 stop of a symmetrical) is given as $\frac{1}{50}$ second; whilst, when the lens is stopped down to $\frac{f}{16}$ (about the No. 4 stop), the exposure ought still to be as little as $\frac{1}{10}$ second. It may easily happen, therefore, that even with a quick shutter such a picture may be rather *over-* than *under-*exposed, and, consequently, may demand the treatment suitable to the former rather than to the latter class. For such negatives the treatment Mr. Crowe lays down for his first class is no doubt exceedingly well suited, although I must confess that my own experience leads me to believe that there is no advantage (and probably no disadvantage) in the preliminary soaking in pyrogallol over plain water, and that the essential point of his developer is rather in the relative proportions of pyro., bromide, and ammonia being especially well suited to the peculiarities of the subject.

I would take, however, as my second class of instantaneous negatives those where, had it been convenient, a longer exposure would have preferably been given, and where only the exigencies of the subject have necessitated an exposure of so limited a duration that objects in motion may not seriously spoil the picture or may even be taken with good definition, such as street views or a train in motion, the latter being a subject which most amateurs have, at some time or other, been tempted to attack. Such negatives, I think, need a different treatment, and the method I advocate is to soak them before developing in dilute ammonia.

I have said that I claim no credit for anything new. I am merely endeavouring to remind the members of what most must already have read, but which, perhaps, may either have been forgotten amongst the multitude of suggestions that are constantly being made, or which some amongst our numbers may never have brought to the test of actual experiment. It is some years ago (I think in the ALMANAC for 1882) since Colonel Stuart Wortley advocated this method of development, without, however, making any distinction between the classes of instantaneous photographs. My only claim in bringing the method forward again is that, being struck at the time with its apparent reasonableness, I forthwith experimented upon it, and think I have obtained better results in that way than I could otherwise have expected.

Probably, the most convenient method of employing this mode of development—at all events of those who use the more scientific method of separate ten-per-cent. solutions—is to add the correct amount of ammonia to the full quantity of water to be employed, and to leave the plate soaking in that whilst measuring out the pyro. and bromide solutions (which may, of course, be in the relative proportions that experience suggests as suitable to the class of subject and make of plate); then return the ammonia solution to the developing cup, and flood the plate with the mixture. Thus, if developing a quarter-plate, and using three grains of pyro., two minims of ammonia, and one grain of bromide—which, I believe, is an average formula—I should take twenty minims of ammonia to one ounce of water in which to soak the plate, and while soaking place in the developing cup thirty minims of pyro. solution and ten minims of bromide solution, return the ammonia to the cup, and finish development in the usual way. In my own practice, however, as I use Edwards's method of developing, in which the ammonia and bromide are mixed in one bottle under the name of "accelerator," I soak the plate in water containing a few drops of ammonia whilst mixing the usual developer, throwing away the dilute solution of ammonia, or keeping it for the next plate, and developing with the mixture in the ordinary way.

In case any of our members should not have employed the sulpho-pyrogallol solution, I may perhaps, in passing, advert to the great convenience of that mode of employing pyrogallol, particularly for an under-exposed plate, where a good deal of forcing may be required. The sulpho-pyrogallol solution permits the addition of a good deal of extra ammonia when necessary, and of a very prolonged development without any staining of the plate. Thinking it might interest the members to see the result of an actual experiment, I took an opportunity, whilst at New Brighton last Saturday, of exposing three plates, with a drop-shutter working in about one-twentieth of a second, on the same subject in rapid succession, so that the light might be presumed to be unaltered. One of these plates then received a preliminary soaking in ammonia and one in pyro., the two being afterwards developed together in the same dish with the same solution. The third plate was developed without soaking in either pyro. or ammonia, but with the same proportions as the other two. Only one half of that plate was soaked in water, the other half remaining dry, in order to test the question whether soaking in water was to be taken as an advantage or a disadvantage.

On developing, the negative soaked in ammonia began to come up in ten seconds, and was finished, as I judged, in nine and a-half minutes from the time of commencing, when it was removed from the developing dish, leaving the other one still developing. The one soaked in pyro. showed no signs of development until eighty-five seconds had elapsed, and was not finished until it had been in the dish for twelve and a-half minutes. The third plate, half soaked in water, began to show signs of action on the unsoaked side in ninety seconds, and on the soaked side not till the expiration of 150 seconds. As it was inconvenient to remove the one half from the dish before the other, both were pronounced finished at the same time, namely, in sixteen minutes.

The result is that the soaked side is perhaps a shade less dense than the unsoaked one, but is, I think, somewhat clearer. A print is before you, and I will leave you to judge which side shows the advantage, if any. In developing these three plates I used Fry's plates and employed Fry's ordinary developer, taking care that each plate was subjected as nearly as possible to the samo treatment. I did not, therefore, vary the solutions, and arrested each when it had attained the same degree of density as the first. It might, perhaps, have been in some respects a fairer test had they all been developed for the same period of time. I, however, exposed another plate to an exactly similar subject at the same time of day but a somewhat different point of view, and that plate I developed according to the best of my judgment, first soaking in ammonia and, when partly finished, adding a double portion of accelerator. This began to come up in ten seconds, was finished in nine minutes, and I think is undoubtedly the best of the four. I place before you for comparison the four negatives and prints from them, and will leave you to judge in which way the difference of quality lies. I must say, however, that, in my opinion, it is less than I should have expected.

Probably the exposure was not very insufficient, as the view was brightly lighted, and I gave about $\frac{1}{20}$th second with an aperture of $\frac{f}{x}$. With less illumination or more rapid exposure the difference between the two methods would probably have been more marked. The fact, however, that one negative attained a certain density in nine and a-half minutes, whereas with the same developer the other took twelve and a-half minutes to reach the same point, seems to me to show considerable gain in sensitiveness, due to the preliminary soaking in ammonia. I intend, however, to try the same comparative plan in exposing and developing two negatives under considerably less light, and should I obtain any additional evidence I shall be glad to report it on a future occasion.

In confirmation of these views as to increased sensitiveness under difficult circumstances of light, I may perhaps venture to call your attention to a print of a plate exposed during our recent visit to Rufford. The light on that occasion was so unusually dull as to cause us almost to despair of getting ordinary pictures, and when inclined to try a drop-shutter picture on a magnificent bull, the mere idea of getting any result seemed almost an act of lunacy. I ventured, however, upon the trial, and, although I certainly cannot say I obtained a picture, yet there is something to show, which would probably be considerably improved by intensifying the negative. So bad was the light that I should scarcely (but for knowing the effects of soaking in ammonia) have been surprised had the plate shown no result whatever, but been capable of being used over again. As Mr. Ellerbeck with a much quicker lens and, I believe, quicker plates (I used Fry's 20 times) took the same subject, perhaps if he would kindly show his result and explain his method of development it would be interesting.

Another experiment bearing upon the same point is as follows:—At Easter of last year I took a very peculiar subject—a deep pot-hole in the limestone district at Settle. Some portions of the hollow were in deep shade. In another portion a stream of water falling over had frozen into a mass of stalactites with a hill of ice underneath, into a basin on the top of which the water fell; this portion and the masses of snow were in sunlight. On this subject I exposed two plates (Edwards's). One, with a stop of $\frac{f}{x}$, received four seconds' exposure; the second, with $\frac{f}{x}$, was taken with the drop shutter. The first was developed by Edwards's ordinary formula, whilst the second was soaked in ammonia. After finishing, the two plates were so much alike that it was difficult to distinguish which was which except by the numbers attached.

I ought to apologise for taking up so much of your time; but as this is an interesting subject, and as the object of adjourning the discussion was to get a fuller expression of the views of the members, I have been desirous to put before you as fully as possible the method that I advocated in the few words I spoke at our last meeting. W. A. Watts.

ON THE SENSITIVE-TO-COLOUR COLLODION PROCESS, OR THE CORRECT REPRESENTATION OF COLOURS BY BLACK PHOTOGRAPHS.*

Precautionary Measures.

In a previous article I have minutely described the mode of operating with stained collodion, and now add the following remarks based upon newer experiments:—1. If two or three per cent. of alcohol should be added to the first silver bath (the sensitising bath), that will prevent the formation of the crescent-shaped streaks, which are produced in consequence of the stained collodion repelling the silver bath more decidedly than ordinary collodion does. 2. When exposing without yellow glass twice the exposure required for ordinary iodised collodion should be sufficient for stained collodion. 3. When exposing through clear yellow glass about five times as long an exposure as for wet iodised collodion will be necessary. 4. Since eosine is alkaline and neutralises the silver bath, and since by its means disturbing organic substances easily find their way into the bath, it is necessary before every time of working that both baths should be tested. A few drops of a one to one hundred solution of permanganate of potassium is added to them; if the rose-red colour disappear at once add a few more drops, and then a third time another few drops until the rose colour remains for a minute. Then test with litmus, and eventually acidify either with glacial acetic acid for bath 1 or with nitric acid for bath 2. With reference to the second bath, it may be observed that it contains the same addition of iodide of potassium as the first.

It has often happened that my pupils, who are already making practical technical use of the stained collodion process, get thick fog and very peculiar granularity with comet-like tails, which have a perfectly frightful appearance. With three drops of permanganate of potassium and a couple of drops of acid the fault was removed in a few minutes, after which faultless plates were obtained.

The Restoration of the Silver Bath.

The organic impurities which arise in the silver bath owing to dyes are more difficult to remove than those which one has usually to combat in photography. In order to render them harmless at length cold treatment with permanganate of potassium no longer suffices. The baths must be heated to boiling-point in a porcelain dish, and then some 1 to 50 solution of permanganate of potassium dropped into it—first, one drop, which usually turns the bath brown immediately; then a second drop is added, and so on. Finally comes a time when the addition of one drop more turns the bath of a rose colour. If this colour remain for half-a-minute stop adding any more of the permanganate solution, filter, and, testing with litmus, acidify again with glacial acetic acid for the sensitising bath and with nitric acid for the developing bath. Permanganic acid is the best of all restoratives of the bath; but many persons are unsuccessful in their use of it because they add too much of the preparation.

Effect of the Granularity on the Pictures.

The slightness of the effect of the granularity of paper, which elsewhere has such a disturbing effect, is a remarkable phenomenon in the case of stained collodion. I have not infrequently taken the same picture successively on ordinary iodised collodion and on stained collodion. In the case of the first plates there was a very strongly-marked and disturbing granularity; on the latter plates, taken with *proportionately exactly equal* exposure, there was often not a trace of granularity. I and my pupils have so often observed this phenomenon that there is no longer any room for doubt respecting it, and this circumstance forms one great advantage of the new process. The explanation of the phenomenon is that the shadows of the grain of the paper are only illuminated by the yellowish reflex light of the studio. This acts on ordinary plates like black, and therefore marks very intensely; on stained collodion plates, on the other hand, this yellow reflex light from the studio walls acts like white, the shadows are not clear but dark, and so disappear.

On the Reproduction of the Colour Scale.

The accompanying photograph of the colour scale, when compared with the reproduction in Vogel's *Lehrbuch*, shows quite surprisingly distinctly the powerful action of the yellow and of several of the green tints. But the action of the madder, the vermilion, and the ultramarine shows better in the silver print than in the lichtdruck print.* In the silver print the tints mentioned are distinctly lighter.

It is the light-green tones that still act somewhat too powerfully; but by the addition of cyanosin, the absorption lines of which lie further towards the yellow, I hope to overcome this drawback. The granular appearance of the colour field is caused by the coating of colour having been unequally taken on. Of course it is understood that the plates were not retouched. At present the dyestuffs that render collodion sensitive to red are not in the market sufficiently pure to justify one in recommending their addition to collodion.

A Final Word.

It is an old and well-known fact that, whenever a discovery is published, there are immediately some people who say that they had discovered this or that before. This is also the case with this stained collodion process. It is certainly quite possible that many persons may have a similar process—as Braun, of Dornach†—because the principle discovered by me is not new; but then they have not pub-

* Concluded from page 341.

* The print of the colour scale referred to here appeared in the *Mittheilungen*.

† Dr. Eder remarks, on page 274 of the *Photo. Correspondenz*, that the firm of Braun, of Dornach, "apparently brought collodion stained with eosine" into the market, but the firm of Braun, of Dornach, have informed the editors of the *Mittheilungen* by letter that such is not the case.

lished the matter, but kept it a secret, and, according to the old axiom, the claim to priority of discovery is considered the due of him who first publishes his discovery. This applies to me also in the case of the process I published for purifying gelatine. With regard to the contention that M. Ducos du Hauron was the first to take through yellow glass: I only remark here that as early as 1873 I used yellow glasses, as anyone may learn by referring to the *Photo. Mittheilungen*, vol. x., p. 237. H. W. VOGEL.

THE SCIENCE OF DEVELOPING-ROOM ILLUMINATION.

Now that the subject of developing-room illumination has been well started in these pages, it would be a public loss should its examination cease before the approximate limits of practical improvement have been reached, so far as present knowledge can go. One point ought to be decisively settled, namely, that it is unscientific to use two or more thicknesses of any deeply-coloured screen of the same material to obtain a safe light in the developing-room. It is true that if feebly-coloured glass or paper be used there may be advantages in using more than one layer of the same material to get fair intensity of colour; but when a substance so deeply stained as the ordinary ruby glass is employed a second sheet gives the extra security chiefly—not entirely—by the general darkening of the room, and a proper screen selected on better principles and with proper illumination should let as much light through as one thickness of ruby glass, and yet be more safe.

Two bad screens, properly selected, are likely to give a safer light than two good screens of the same kind of glass. For instance: suppose a photographer to possess a tolerably safe sheet of orange glass and a tolerably safe sheet of ruby glass, and that these two sheets could be split into four, each of half the previous thickness, the superposition of one of the thin orange upon one of the thin ruby sheets would be likely to give a safer light than either colour before gave by itself, for the simple reason that one of the combined sheets is likely to cut off many of the particular rays which were doing mischief through the other, and this advantage is gained with scarcely any loss of light by the general darkening of the room.

As a rule for practical guidance, with coloured screens of ordinary intensity there is no doubt that two layers of the same glass should never be superimposed to get the best results. Whether the molecules of the one material be in the solid, liquid, or gaseous state, the first fairly-coloured layer does most of the sifting of the beam of white light, and the next layer is in greater part transparent to the previously-transmitted rays, except by darkening the room. In experiments on the transmission of light through ice—such as setting fire to a substance by rays brought to a focus by a lens of ice—it is usual to first pass the beam from the electric lamp through a plate of ice or through a layer of water. In the former case the plate melts rapidly; in the latter, which is the better method, the water becomes nearly boiling hot, but the sifted beam is in both cases practically cold, so far as its action on the ice lens is concerned. The substance ignited, however, by the sifted beam which will not melt ice without great delay, becomes hot because it absorbs rays to which ice is transparent, just as glass of one colour will absorb some of the rays to which glass of another colour is transparent, as already stated. These are established facts of physics.

Unground glass, I am convinced, should not be used at all for a lantern screen to get the best results, which is the reverse of what might be expected without previous attention to the subject, as its preferable substitute—paper—is full of minute holes. The reasons for this conclusion were given in my last article on this subject.

The Editors have favoured me with a piece of the remarkable green sheet gelatine made by Mr. Woodbury, a few superimposed thicknesses of which are green by transmitted light, whilst many superimposed are red. In the spectroscope a few layers of the specimen cut off all the yellow, orange, and yellowish-green rays, but permit plenty of red, as well as most of the blue and violet and bluish-green, rays to pass. Hence when many thicknesses of this green medium are superimposed the delicate blue and violet rays are gradually absorbed, until at last, with a three-parts opaque set of layers, only the red rays can force their way through, but the transmitted light is then feeble.

Coloured materials which cut much out of the middle of the visible spectrum, but allow the two ends thereof to pass, often present curious optical phenomena. One of these is a solution of cyanine, which possesses the blue of the corn-flower by daylight and a bright violet colour by gaslight—the light in which it is so difficult to exhibit a bright violet. The violet of cyanine is not, however, for the most part a true violet, but a violet made up chiefly of blue and red, as revealed by that optical policeman—the spectroscope. Hence, as daylight wanes and gaslight takes its place, the chemical rays become less plentiful, the red in the cyanine gains more proportional ascendancy, and the liquid assumes a rich violet hue. These effects afford a strong argument in favour of yellowish artificial light in place of daylight behind the coloured screens used in photography, since the chemical rays so preponderate in proportion in daylight as to thus change the colour of particular exceptional screens of a given thickness from the colour they possess by gaslight.

A five-per-cent. solution of chrome alum in cold water, as pointed out to me by the Editors, possesses curious optical properties. A moderately-thin layer of the solution transmits greenish-blue rays; a layer two or more inches thick appears red when viewed by transmitted light. If the solution is in a bottle of somewhat large diameter it is but necessary to turn the bottle upside down; the liquid in the neck will appear to be of one colour by transmitted daylight, and that in the larger part of the bottle of another colour. As in the cyanine example, it is a liquid which absorbs much of the middle of the visible spectrum, so that when the thickness of the layer is increased most of the blue and violet rays are absorbed; the green and yellow have been absent all along, and therefore the red, for the most part, find their way through. The red light, however, is then not bright and strong; the safety from the blue rays has been largely purchased at the cost of general absorption—in other words, by piling on an undesirable amount of relative opacity, as in superimposing two sheets of ruby glass.

With a saturated solution of cyanine in alcohol and water the thickness of the layer of the coloured liquid matters little; it is simply blue by daylight and violet by gaslight. Its value in Dr. Vogel's new experiments consists in its power of cutting off the yellow, green, and some of the red rays of the spectrum. The greens which are of any use as fundamental screens in developing-room lanterns are yellowish-greens, and not bluish-greens. They must also be true greens, and not greens produced by mixing yellow and blue colours; therefore, many bad greens are readily available, which perhaps has been the cause of the absence hitherto of general utilisation of green light in the developing-room. Good greens for the purpose can easily be discovered, and selected from a number of samples, by means of a polychromatic negative.

Arguments drawn from photographing coloured papers or ribands are valueless as applied to spectroscopic problems, because the violet may not be a true violet, but a mixture of red and blue; the green may not be a true green, but a mixture of blue and yellow, and so on with other tints. Had the dyer used colouring matters of another chemical composition the photographic results might have been different. If the rays thrown off by the ribands were to be first analysed by the spectroscope to ascertain their real nature, arguments resting upon such a foundation would begin to be of value.

Mr. A. Pringle's statement that the great extra safety obtained by allowing the light to fall upon the solution in the developing-dish at a low angle means so much light withdrawn from the illumination of the plate under development is quite correct. The advantage is that by moving the dish five or six inches nearer to the lantern more light on the plate can be had, *if* wanted and *when* wanted; and I find it safe to develope in that bright light all the way through. Still, the moving of the dish six inches away to gain the two very great additional elements of safety—namely, low angle of incident light and increased distance from the translucent screen — gives a feeling of absolute security which is psychically soothing. With extremely-sensitive plates attention to these two latter points might be more necessary.

As coloured oiled silk is not made in England could not the tracing-linen used by engineers and surveyors be stained? Glass is not translucent, ordinary papers and fabrics are too thick, and thin papers too irregular. What is wanted is plenty of choice, on the part of the purchaser, of many varieties of green, orange, yellow, and red. The latter colour, I believe, will go out of general use for practical photographic purposes unless it be modified by a companion layer of green; but yellow and green are likely to give light more for the benefit of the eyes. I hope Mr. W. E. Debenham will bring up some better screens and more suitable lights at the next meeting of the Photographic Society of Great Britain, for he has not yet reached the limits of possible improvement; and it would be a pity to stop half-way to continue his antagonism with the solar spectrum.

This article is written to show reasons for further advance where good authorities are now stopping short. Week by week good authorities in photography admit their use of two thicknesses of ruby glass; the point herein advocated is that on other principles they can get equal safety with all the illumination of less than one sheet of ruby glass. A good authority, Mr. Pringle, says that the chemical and other visible rays are in the same relative proportion in daylight and in ordinary artificial white lights, which is herein denied. The brilliant oxyhydrogen lime-light and its poverty (too much generally over-estimated) in chemical rays is an additional case in point. If my views are right—and they can be experimentally tested—Mr. Debenham's good light is only on the road to the brighter light of the future, which he ought to be the man to introduce instead of quarrelling with the spectrum.

W. H. HARRISON.

EXPERIENCES ON THE THAMES.

"WHERE to go with the camera" and obtain pretty little picturesque "bits" has often been a puzzle to myself and, as far as I know, to many others to solve. With my friend, who will figure in the following *Experiences on the Thames*, I have made several excursions. One time we visited Eltham to get pictures of the fine old ruined abbey, said to have a long historical past. The abbey is picturesque enough in its way, and so is the pond close by the station; but as its tranquil surface is broken by neither swan, duck, nor boat, our subjects were still life only. The results we obtained did not come up to the ideal we expected.

Another time we tried Box Hill, with its pretty villas and cottages nestling amongst umbrageous bowers; its rippling, meandering stream bounded by overhanging trees; and its fresh, sparkling waters covering

"Here and there a lusty trout,
And here and there a grayling."

Here and elsewhere on our rambles we have obtained a few interesting negatives; but we longed for something more, and were, moreover, eager for adventure and novelty. At length an opportunity occurred to myself and friend—who I will henceforth refer to as the "Philosopher" (for he always did the philosophising *en route*)—to "do" the Thames from Oxford to Windsor. It took us a long time to make up our minds to do the trip, and it took us a still longer time to make up our minds "how to do it." We often regretted we had such a mental superfluity.

First, the idea of a steam-launch naturally occurred to us. We thought and dreamed of the pleasure we should have in skimming along the tranquil surface without any labour of rowing. We would sleep on board, cook our own provisions, and be independent of rapacious hotel-keepers. One fatal objection was urged against such a course: we feared we might be so enthusiastic and absorbed in our search after the picturesque scenery of the Thames that we might forget all about the boiler, and a blow-up might happen in consequence. This, we argued, would cause us a considerable amount of inconvenience and a needless destruction of valuable apparatus; we, therefore, reluctantly gave up those dreams of luxuriating on the Thames in a steam-launch, deciding at last to go in for a small boat, and we wrote to Salter's, at Oxford, to arrange for the hire of a suitable vessel (the "Philosopher" always dignified our boat by the name of "vessel").

At length the morning of starting arrived, but it rained in such quantities and blew such a gale that we were naturally "found wanting." However, next day it cleared somewhat, and at 9 a.m. we were at Paddington, in the main-line express, bound for Oxford, *viâ* Didcot, arriving at our destination about two hours later. Leaving our luggage at the station we had a look at the town.

The antiquity of Oxford is pretty remote, and is probably as great as that of any other English city. The early chroniclers never worried themselves about facts when fiction was equally acceptable. One of them, who was burdened with a large amount of inventive ingenuity, was an ecclesiastic named Geoffrey of Monmouth. This worthy man, who lived in the twelfth century, gives us a very fanciful and amusing account of the founding of this city. He declares Oxford to have been built originally in 1009 B.C.—more than 250 years before Romulus founded a city on the banks of the Tiber—by Memphric, King of the Britons, "upon the ryver Temes," and, therefore, "deserves to be reckoned not only amongst the first and most autient cities of Britain, but of all Europe and of the world." However, we know it suffered much at the hands of the Saxons, was burnt by the Danes, and ever suffered severely during the internecine wars from the Conquest to Charles I. To its university Oxford owes its fame. It is asserted that in the ninth century it had become a fountain whence issued many learned clerks; and that amongst the earliest to endow it was King Alfred. The separate erection of colleges for the special accommodation of students did not commence until the middle of the thirteenth century. Merton, Balliol, and University are the eldest, being founded between the years 1264 and 1300. Altogether there are nineteen colleges in Oxford.

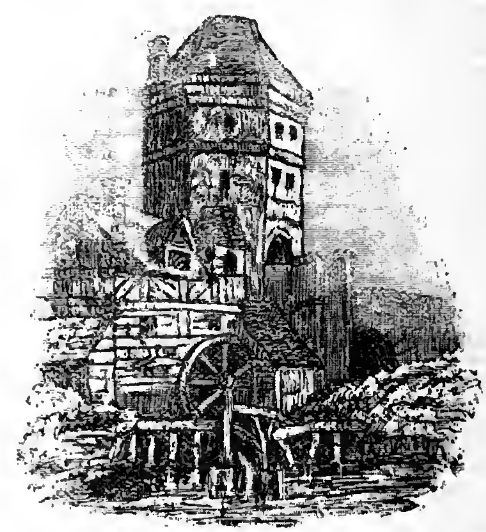
"Ye fretted pinnacles, ye fanes sublime,
Ye towers that wear the mossy vest of time;
Ye massy piles of old munificence,
At once the pride of learning and defence;
Ye cloisters pale that, length'ning to the sight,
To contemplation step by step invite;
Ye high-arch'd walks, where oft the whispers clear
Of harps unseen have swept the poet's ear;
Ye temples dim, where pious duty pays
Her holy hymns of ever-echoing praise;
Lo! your loved Isis, from the bord'ring vale,
With all a mother's fondness bids you hail!
Hail! Oxford, Hail!"

The arms of Oxford are emblematical of the city's name, being an "ox crossing a ford." At length, after being duly impressed with respect for those venerable piles of colleges at that ancient seat of learning, we reached Salter's, where we had hired our boat. We were somewhat anxious about our vessel; for we had been liberally entertained with dreadful stories of accidents to small boats, and several kind friends had even requested us to make our wills in their favour and then "never mind." We inquired for the manager and asked him to show us our vessel. He apologised; that being Henley week he had not quite such a large choice to offer us, at the same time showing us several which, from their delicate taper and want of width of beam, simply shocked our nerves. He asked us what we did want. We told him we had a very large cargo of valuable apparatus, besides baggage, including waterproofs, rugs, vast quantities of dry plates, cameras, cooking utensils, &c.—in fact, all the paraphernalia for a regular campaign, all more or less valuable, and we wished to risk nothing. What we wanted was a kind of elongated tub, or, more properly speaking, something of the lugger type. Our man thought he understood and selected the most tub-like form he had in stock. As he had nothing broader we were forced to be content, and forthwith gave orders to have her fitted up with awning, for protection from the sun (which rarely shone), and all the usual gear of sails, mattresses, towing line, &c.

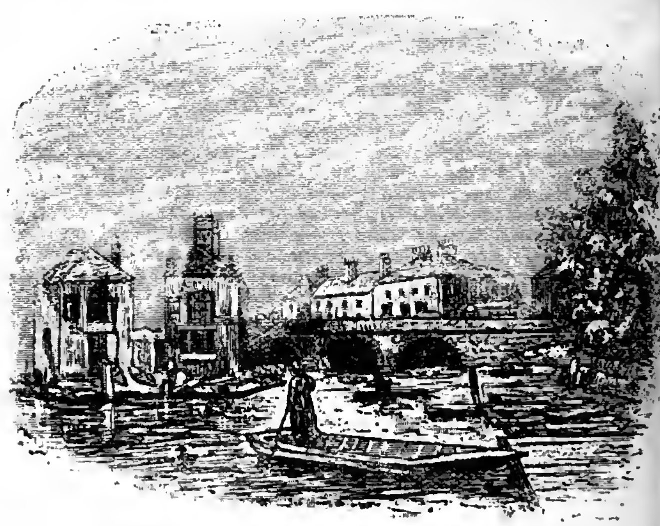
This important business completed, we took a more tranquil look at the university town, and regretted we could not spare time to have a few "shots" at the various colleges, for we were convinced we might get some very interesting negatives.

After making further purchases of provisions, including eggs—which, unfortunately, very soon got into a leaky condition, much to our discomfiture—we got back to Salter's in the afternoon.

Our first act was to have a "shot" at Folly Bridge. Friar Bacon's study, which forms the subject of our first illustration, formerly stood



on the bridge "near the end next the city," but was taken down in 1779. It is traditionally narrated that to this tower the great Roger Bacon, one of the greatest luminaries of the middle ages, used to resort at night "to take the altitude and distance of the stars." Popular prejudice accused him of magic, and he was sent to Rome by the general of his order to answer his charge, but, having cleared himself, was sent back to England. The second illustration is the picture which we



took. The Philosopher manipulated the camera, whilst I posed myself in a punt so as to form an attractive foreground. We had carried several rigs-out in the way of changes of garment and hats, so as not to be recognised as "that same individual again," and we even went so far as to purchase a couple of decoy ducks, and these added variety and "charm" whenever the foreground was a weak one. The Philosopher wanted to get one or two decoy swans. I have no doubt this was a good idea, but, luckily for our comfort, they are not manufactured. Many other pictures we got in this neighbourhood, which included views of the university barges down the stream, the Grand Pont, &c., and, as we had Salter's boats at our disposal, we had no difficulty about foregrounds. At length, though rather late in the day, we got ready for the start; but meanwhile the wind—which had already caused us serious interruption in our camera work (one camera narrowly escaped going to the bottom)—blew a regular white squall. We were getting quite nautical by this time. However, we got our baggage and apparatus on board, but our enthusiasm was rapidly running down to zero.

We had started and had proceeded for about a couple of hundred yards when one of us whispered whether it would be wise in face of such a "gale" to keep on. We stopped to argue the point, but just then an extra gust came which carried away several things out of the vessel and one of our hats. This decided the question; so, after collecting what we could, we beat a hasty retreat back to Salter's, deciding to make an early start on the morrow. For the rest of that day our cameras remained idle.

In the evening we developed a few of our plates and found we had hit the exposure fairly correctly. Circumstances necessitated a rapid exposure; we could rarely give more than a-quarter of a second. Our plates registered 22 on Warnerke's sensitometer; and we found that, with a rapid rectilinear lens and the No. 5 stop, a-quarter of a second was quite sufficient for sunshine, whilst for a picture without sun we either used a No. 3 stop or exposed longer—usually the former alternative, for we had rarely a chance, in consequence of the windy weather, of giving more than a-quarter of a second.

J. J. Acworth, F.I.C., F.C.S.

(To be continued in our next.)

THE ROYAL INSTITUTION.

The Production of Coloured Lights.

On Thursday, the 22nd ult., Professor Dewar delivered another of his series of afternoon lectures at the Royal Institution, on *Flame and Oxidation*, in the course of which he exhibited apparatus for producing coloured flames, which would be of use in obtaining coloured lights for experiments in developing-room illumination. Hydrogen burns with an almost non-luminous and colourless flame, its tinge of yellow being chiefly due to impurities in itself and in the air, in the shape of floating particles of soda salts; but this tinge is not deep enough to do harm in the application of his apparatus to the purposes just suggested.

The apparatus consists of a kind of "spray-producer," by which the gas is first charged with particles of any desired salt in solution, and then conducted to the burner.

To obtain a steady flame a steady blast of gas is necessary. At the Royal Institution hydrogen, compressed in an iron receptacle, is used; but any other arrangement which gives pressure enough will answer the same purpose.

Professor Dewar charged the hydrogen gas with solution of chlorochromic acid. This gave a brilliant white flame, rich in rays which act on photographic films. It also gave off a white smoke, which, on being collected on a white plate, was seen to really consist of green particles of oxide of chromium; indeed, the plate was coloured a bright green. By means of a salt of sodium he gave a yellow colour to the flame, and to himself a ghastly appearance. In short, the apparatus affords a ready means of keeping up a steady and large coloured flame when the operator has a steady supply of hydrogen at sufficient pressure. It is better than the old-fashioned plan of colouring a spirit flame by salts dissolved in the alcohol, because many salts will scarcely dissolve therein at all; and when they do, and are not volatile, they often clog the wick, and do not find their way in any great quantity into the flame. The construction of the spray-producing part of Professor Dewar's apparatus is a very simple matter of glass-blowing.

In the course of some experiments on increasing the luminosity of flames, Professor Dewar proved that increasing the quantity of air would, under certain conditions, increase instead of decrease the light of a Bunsen's flame. He directed a jet of air into a Bunsen's flame, and, when a particular steadiness and pressure of air-blast had been reached, the air coloured the flame green where it passed through it. He also exhibited Frankland's experiment of burning an oxyhydrogen flame under pressure, and its luminosity increased with the pressure. From this Frankland argued that the luminosity of flame does not necessarily depend upon particles of solid matter liberated in the flame, for in this experiment no solid matter is present. Professor Dewar said that there is some truth in Frankland's hypothesis that the luminosity of flames is due to highly-condensed gases, and a great deal of truth in Davy's original hypothesis that the luminosity is due to liberated particles of carbon or other solid matter in the majority of cases. He next proved that the luminosity of the electric spark increases under extra pressure of air, but said that the result might be explained by a variety of hypotheses, so that its real cause is difficult to unravel.

The lecturer further stated that some hydrocarbon compounds enter, like paraffine, into combination with other substances with difficulty; others, like olefiant gas, acetylene, and naphthaline, are easily decomposed, or easily enter into new combinations. In illustration of this he experimentally proved that a small quantity of bromine will quickly absorb a large volume of olefiant gas, and also that bromine readily unites with naphthaline, giving off vapour of hydrobromic acid in the act.

Professor Dewar remarked that in scientific research it is sometimes necessary to use a flame free from superheated steam. Such a flame can be most readily obtained by burning a jet of chlorine and hydrogen, mixed near the nozzle of the burner, for safety, and care being taken to carry off the hydrochloric acid gas, which is the product of the combustion.

Photography Applied to Sidereal Astronomy.

On Friday, the 23rd ult., Mr. David Gill, F.R.S., H.M. Astronomer at the Cape of Good Hope, delivered an evening lecture at the Royal Institution, on *Recent Researches on the Distances of the Fixed Stars*. Lord Rosse presided, and among the listeners were Professor Huxley, Professor Tyndall, Dr. Huggins, Lady Arthur Russell, Mr. William Crookes, Dr. Edmunds, Professor Dewar, and Dr. Mann. There was a large attendance altogether.

Mr. Gill began by stating that the study of sidereal astronomy is particularly fascinating. We gaze upon the galaxies of suns which surround us, and wish to learn whence we come and whither we are drifting in the realms of space, and what is the position of our own sun in the starry host. Are the nebulæ for ever to retain their ghostlike forms, or are they condensing into suns? The discoveries of the past prove that "art is long and life is fleeting," and that in the long run careful observation will do more than the most brilliant speculations. He would not, however, undervalue the imaginative faculty; for nothing else would sweeten the dreary watches of the night and make the work of the astronomer a labour of love. He then spoke of the distances of the fixed stars, so far off that before 1832 all attempts to measure the distances of any of them had failed, and then information began to be gained by comparing small changes in their position in relation to other stars apparently near them. Henderson, of the Cape Observatory, was the first to obtain the parallax of a star by direct measurement, and the distance of the stars is so great that it is customary to state their position by the time light takes to travel from them to the earth. Light takes 500 seconds or 8⅓ minutes to come from the sun to the earth; this estimate of the time is probably right within one second. The distance of the sun from the earth is about 93 millions of miles; this estimate of distance is probably correct within 200,000 miles. The time in which light travels to the earth from other fixed stars than our sun has to be expressed in years, the other stars being so far off. He and a young American astronomer, Dr. Elkin, had for two years been measuring the distances from the earth of some stars in the southern hemisphere, by means of a telescope with a divided object glass, the two halves of which could be placed at measured angles in relation to each other. The result of their observations was that light was 4·36 years in travelling from Centauri to the earth; 8·6 years from Sirius; Lacaille (9352) 11·6 years; E Indi, 15·0 years; O 2, Eridani, 19·0 years; Eridani, 23·0 years; Tucanæ, 54·0 years. The broad conclusions at which they had arrived were that neither the apparent size nor apparent proper motion of a star gave any true idea as to its distance from the earth. Mr. Warren De la Rue was the father of the application of astronomy to photographic observations, and his results were well known to all present. Of late years great strides have been made in the chemistry of photography, especially in methods of manufacturing highly-sensitive dry plates, so that photography is increasing in its power of giving aid to astronomy.

The lecturer then exhibited on the screen, by the aid of the electric lamp, some photographs of the great nebula of Orion, taken at Ealing. The time of exposure of the plates had varied from one minute to one hour, the latter giving a splendid representation of Orion. No hand of fallible man (said the speaker) had touched these representations; the soul of the artist was not in them, but so much the better for science. Elaborate drawings of Orion had been made and engraved in the past; but a hundred years hence, if astronomers were given the choice between the destruction of all the engravings or of the photographs he held in his hand, he thought they would vote unanimously for the preservation of the photographs at the sacrifice of the drawings. Was it not, then, the duty of the scientific world to begin the photographing of the heavens? Did not future generations demand the performance of the work as a duty to them? A photographic library of the heavens was wanted, but the work must be done by proper instruments made for the purpose; and it was a work which must be done on a national scale. Mr. Norman Lockyer had recently declared that the future of astronomy lay in photography, and had laid a proposition in practical form before the Royal Astronomical Society. Mr. Lockyer also considered it to be the duty of the nation to take up the work. He (Mr. Gill) would conclude his remarks by quoting the words of Sir John Herschel—words as beautiful as they were just, and uttered in the early days of stellar astronomy, when the strongholds of space were just beginning to yield to scientific research. What a pleasure it would have been to Sir John Herschel, could he have seen the photographs of the nebula he so laboriously studied! The following words of Sir John Herschel were uttered forty-two years ago, in presenting the medal of the Royal Astronomical Society to M. Bessel, for his researches on the annual parallax of the star 61, Cygni:—"Such results are among the fairest flowers of civilisation. They justify the vast expenditure of time and talent which have led up to them; they justify the language which men of science hold, or ought to hold, when they appeal to the governments of their respective countries for the liberal devotion of the national means in furtherance of the great objects they propose to accomplish. They enable them not only to hold out but to redeem their promises, when they profess themselves productive labourers in a higher and richer field than that of mere material and physical advantages. It is, then, when they become (if I may venture on such a figure without irreverence) the messengers from heaven to earth of such stupendous announcements as must strike every one who hears them with almost awful admiration, that they may claim to be listened to when they repeat in every variety of urgent instance, that these are not the last of such announcements which they shall have to communicate—that there are yet behind, to search out and to declare, not only secrets of nature which shall increase the wealth or power of man, but truths which shall ennoble the age and the country in which they are divulged, and, by dilating the intellect, react on the moral character of mankind. Such truths are things quite as worthy of struggles and sacrifices as many of the objects for which nations contend and exhaust their physical and moral energies and resources. They are gems of real and durable glory in the diadems of princes, and conquests which, while they leave no tears behind them, continue for ever unalienable."

PATENTS APPLIED FOR.

No. 8,351.—"Photographic Apparatus." S. M. Messinesi, 16, Philpot lane, E.C.—*Dated May* 28, 1884.

No. 8,463.—"Photographic Cameras." S. D. McKellen.—*Dated May* 31, 1884.

No. 8,470.—"Photographic Camera for Travelling Purposes." J. Joyner.—*Dated May* 31, 1884.

New Apparatus for the Exposing of Photographic Sensitive Plates in Cameras.

This is the specification of John and Alfred George Hopkins, of Hoddesdon, Herts.

Our invention as above, to be designated hereafter as the simplex slide and reversible camera back, consists of a perfectly light-tight box or slide, made so as to receive the plate in a carrier, which said carrier is made to run in grooves in slide, and which cannot get displaced when putting in or taking out plates. This said slide is made perfectly impervious to light by means of a simple lid affixed to the plate carrier, in such a manner that when the said carrier containing sensitive plate is pushed home into the slide, and by means of a simple turn of screw let in on top of slide into a screwed plate on plate carrier to keep it fixed, it becomes perfectly proof against light. The camera back is so made, with an opening on top the exact size of the plate slide, which, when exposure is to be made, it is fixed thereto by means of two levers each side of back inserted in small grooves made in plate slide, which by this means makes the whole perfectly rigid. The exposure of plate is made by simply removing the small screw on top of slide, and inserting a rod with screw at end, so as to screw into plate carrier, by which means the plate is let down or drawn up at will of operator; the said rod to be just the length of slide, so that by simply pushing the plate carrier down in grooves into the said back the sensitive plate is kept in position by means of a spring, which is attached to back of plate carrier. The plate is then ready for exposing. The camera back is made with a door, so that the focussing-screen can be inserted or taken out without interfering whatever with plate slide when attached to camera back, so that the focussing of a subject and exposure of plate on same becomes a most simple and very easy method and very quickly done.

Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, we declare that what we claim is—

1. The plate carrier, with spring back and light-tight lid affixed.
2. The slide or box to receive plate carrier.
3. The arrangement of rod, with screw end passing through top of slide into a screw plate on carrier, for bringing into position the sensitive plate into camera back for exposure and then also into slide after.
4. The arrangement of the screw passing through top of slide into screw plate of carrier, for keeping slide impervious to light when closed.
5. Reversible camera back, made with an opening to receive plate slide.
6. Levers on camera back, for making slide quite rigid when brought into grooves of slide.
7. Method of inserting focussing-screen into camera back without interfering with slide while attached to the back.
8. The camera back can be made to fit any camera, and any number of slides can be used with same.

Contemporary Press.

A SIMPLE TEST FOR THE DETECTION OF A BROMIDE IN THE PRESENCE OF AN IODIDE.

[English Mechanic.]

When chlorine or chlorine water is added to a soluble iodide in the presence of starch or dextrine, the well-known violet-coloured iodide of starch is produced, this compound being destroyed by excess of chlorine, owing to the formation of chloride of iodine. A solution of bleaching powder or of sodium hypochlorite behaves in a similar manner when substituted for the chlorine or chlorine water.

When chlorine or chlorine water is added to a soluble bromide in the presence of starch or dextrine a yellowish-brown or brown colouration is produced, according to the amount of bromide present or to the state of its dilution. This colour is not so easily destroyed by excess of chlorine. With a solution of bleaching powder or of sodium hypochlorite no colouration is produced until an acid (in most cases dilute sulphuric acid is preferable) has been added, when we get the ordinary colouration due to bromide.

Upon this fact depends the following simple test for the detection of a bromide in the presence of an iodide:—To the solution containing an iodide and a bromide starch or dextrine is added, and then a drop or two of solution of bleaching powder or of sodium hypochlorite, when the violet colour indicating the iodide appears. Sufficient hypochlorite solution is now added carefully to produce the chloride of iodine, or until the blue colour disappears. Then, on the addition of dilute sulphuric acid, the brown colour indicating the bromide is at once brought out.

The bromide reaction is by no mean so delicate as that of the iodide, but from experiments made it was found possible to detect $\frac{1}{50}$th of a grain of bromide of potassium when mixed with $\frac{1}{100}$th of a grain of iodide of potassium in a concentrated solution, and $\frac{1}{8}$th of a grain of the bromide in the presence of $\frac{1}{10}$th of a grain of iodide when dissolved in one fluid ounce of water.

The test was applied to the concentrated fluid obtained by the evaporation of twenty ounces of sea water to the bulk of three ounces, and an excellent result was obtained. A similar experiment with 1,000 grains of sea water was also made. In this case the salts deposited were removed, and the mother liquor concentrated to a very small bulk. On applying the test there was an abundant indication of bromide.

The test has also been applied when the iodide and bromide were mixed with salts of the following metals, viz.:—Potassium, sodium, ammonium, aluminum, zinc, and magnesium, with excellent results. With barium, strontium, and calcium the reactions were distinct, but on account of the precipitated sulphates when dilute sulphuric acid is employed the colour of the bromine is not so definite. Hydrochloric acid may in such cases be substituted for sulphuric acid, and excellent results obtained. With salts of chronium, iron, manganese, nickel, and cobalt the test cannot be applied. If a bromide or an iodide should be present with these metals they can be detected by first precipitating the metals by means of potassic hydrate, and then examining the filtrate in the usual way.

Also in the presence of the following salts of the alkali metals—sulphates, chlorides, phosphates, carbonates—with satisfactory results. With soluble sulphides an opalescence occurs due to precipitated sulphur, which hides the bromide reaction. The iodide is also unworkable in the presence of a sulphide. If, however, the sulphide is precipitated by zinc sulphate solution, the filtrate may then be employed to detect both the bromide and and iodide with excellent results. With chromates the reactions are also indefinite. In this case the chromic acid may be reduced by sulphurous acid to chromic oxide condition, then precipitated by potassic hydrate, and the filtrate examined for the bromide and iodide.

In the presence of a chloride the bromide is tested for in the same way, and, having the chlorochromic acid test specially for the chloride, this test leaves nothing to be desired in the detection of these three acids when mixed in a solution.

University of Aberdeen.

Our Editorial Table.

The Royal Academy Illustrated.

London: Chapman and Hall.

In this, the first of a new series of illustrated guides to the Royal Academy, Mr. Henry Lassalle has collected together nearly two hundred of the principal works of art in the different classes in this year's collection. The work resembles more in its character the *Illustrated Catalogue of the Paris Salon* than our own *Academy Notes*, the illustrations being for the most part of full-page size, and have been reproduced by a photographic process from the sketches supplied by the artists themselves. We learn from the editor's preface that the idea of the work was only conceived a few days before the opening of the exhibition. The task of collecting together in so short a time so large a number of pictures must, therefore, be considered to have been carried out in a most admirable manner; and it may be hoped that, with more time in future years and the increased facilities brought by experience, Mr. Lassalle will be able to achieve even greater success.

All About Derbyshire.

Derby: R. Keene.

This is a pretty volume of nearly 400 pages, consisting, as the preface informs us, of a number of occasional articles contributed to various journals by Mr. E. Bradbury descriptive of Derbyshire scenery. Mr. Bradbury's name is not unknown to our readers, he having contributed one or two articles to our *Where to Go with the Camera* series last year. His style is clear and pleasant, and the character of the book is as far removed from the matter of fact "guide-book" pattern as it is possible to be conceived. The work is profusely illustrated by woodcuts and photographs, the latter consisting of full-page platinotype prints produced from his own negative by the publisher, Mr. R. Keene, whose photographs have also been utilised by the wood engraver. The book will form an elegant addition to the libraries of lovers of English scenery.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 27th ult., the chair was occupied by Mr. A. L. Henderson.

Letters were read that had been received from Mrs. H. Baden Pritchard and from the daughter of the Rev. F. F. Statham acknowledging letters of condolence which had been sent by the Society.

A communication was also read from Mr. Berryman, in answer to one that had been written by Mr. A. Haddon, Curator of the Society, requesting a lecture and demonstration of the enamel process as practised by Mr. Berryman. This gentleman's reply consisted of a promise that he would in the autumn comply with the request of the Society.

Mr. A. COWAN said it had often been stated that the addition of chrome alum to an emulsion had the effect of slowing development; it had also been asserted that it made the emulsion slower—that is, less sensitive. He now produced two negatives which had been similarly exposed and developed together in the same dish. The one plate had been coated with an ordinary emulsion; to the other chrome alum in the proportion of one grain to eight ounces had been added before coating. There was no noticeable difference between the two negatives either in apparent sensitiveness or density.

The CHAIRMAN had always found that a soft gelatine gave greater sensitiveness than a hard one; there might, however, be great advantage in the use of chrome alum, as development could then be conducted warm. He requested Mr. Cowan to try the effect of hot, weak solutions on the plates and to report the result.

Mr. W. COBB remarked that chrome alum solution required to be very carefully mixed with the emulsion or it would cause parts of it to become gelatinised. He had obtained some of his most sensitive emulsions when using a hard gelatine.

Mr. W. E. DEBENHAM said his experience was similar to that of Mr. Cobb's.

Mr. W. M. ASHMAN thought that in the case of the negatives shown the point was that sensitiveness had been obtained before the chrome alum was added. A small quantity of this salt did not render gelatine insoluble, as was exemplified in a solution used as a substratum. Mr. Cowan had proved that, even if the gelatine were hard, development went on all the same.

Mr. COWAN had received a letter from a gentleman whom he had instructed in the emulsion process, and who was now at the Cape of Good Hope. The writer mentioned having a batch of emulsion the gelatine in which, from long keeping, had become decomposed and useless; upon adding fresh gelatine it had given pictures surpassing in quality and rapidity those that had been obtained from it in the ordinary way.

Mr. COBB said that this pointed to the desirability of allowing the gelatine to become decomposed.

Mr. H. S. STARNES suggested the use of a very small quantity of gelatine, and of allowing it to become entirely decomposed.

The CHAIRMAN said that if either a hard gelatine were used or the chrome alum added to an emulsion the result would not be affected thereby, provided the plate were soaked before the commencement of the development; but if pyro. were used in the first instance the film became parchmentised. It was found that the addition of metagelatine to an emulsion induced greater speed.

Mr. STARNES described a dark slide made of sheet tin, which he would produce at a future meeting.

The CHAIRMAN referred to two developed but unfixed plates that had been shown at the previous meeting. To prevent development from going on, these plates had been for a short time immersed in a solution containing a small quantity of bromide of potassium and of nitric acid. The effect of this had been that the image was reduced, and, indeed, it happened in the case of the more powerful image that it was removed altogether. He (the Chairman) then showed a clamp, which had been lent him by Mr. F. York, to be used instead of a camera-stand, in places where the employment of the latter would be impracticable. It consisted of a top with screw for attachment to the base of the camera, connected by means of a universal joint with a cramp for fixing to a window sill, the edge of a vehicle, or any convenient support. He also showed a negative taken the previous day, at Epsom, of the horses starting for the Derby.

Mr. DEBENHAM then exhibited a lantern to demonstrate that composite white light might safely be employed for developing purposes. In the sides of the lantern were two paraffine lamps—one glazed with glass of a yellowish-green colour and the other with a sheet of stained-red. The light from these lamps was not allowed to fall upon the front of the lantern direct, but was received on a sheet of white cardboard curved to fit the back of the lantern, over the front of which a sheet of tissue-paper was stretched. To compare the light thus produced with that resulting from reflection only—and which it had been said was sufficiently safe for developing purposes—the coloured screens were removed from the lamps and the wicks turned low. The light from the front of the lantern was then to the eye very similar to the composite light first exhibited. A variation was now shown by means of which still greater safety could be attained. The coloured glasses were re-inserted, but a sheet of yellow paper was substituted for the white cardboard employed as the reflecting surface in the first experiment. The yellowing effect to the eye resulting from this change was less than might have been expected.

In order to test the photographic effect of these lights several of the members—including Mr Ashman, Mr. J. J. Briginshaw, Mr. J. Cadett, Mr. Cowan, Mr. Debenham, and some others—adjourned to an adjoining darkened room. Mr. Cadett was selected to decide the distance at which he could read ordinary print for each of the lights to be tried, the wicks, however, being so adjusted as to make these distances as nearly as possible equal. Mr. Ashman exposed a portion of a plate—which had been supplied by Mr. Cowan for the purpose—full square to each light, for a period of one minute, at the reading distance as found by Mr. Cadett. The plate was then developed in the appliance exhibited by Mr. Debenham at the previous meeting, and handed round to the members. A strong impression was found to have been produced by the reflected light, when used without coloured screens; but no trace of an image had resulted from exposure to the composite white light, reflected either from the white cardboard or from the yellow paper. In reply to a question,

Mr. COWAN said that the plate just used was one registering 19 on the sensitometer.

The CHAIRMAN said he would now repeat the experiment he had shown some time previously at a meeting of the Society, and which had been sneered at at the time as unscientific, but which he considered to be the same in principle as the composite light just shown. The idea, he might say, he had obtained from Mr. J. W. Swan. Two gas jets were lighted—one turned low, and the other surrounded by a globe of ruby glass. An opaque object was then placed in such a position as to cast side by side shadows from the two burners upon a paper screen. One of these shadows was, he (the Chairman) observed, red, and the other green. If the light proceeding from these portions of the paper were combined a compound light would be produced similar to that shown by Mr. Debenham.

Mr. DEBENHAM pointed out that the shadow from the red light only appeared green by contrast. The green-looking space was simply illuminated by the uncovered burner, and to use the light from this in conjunction with that from the red covered light would only be to use white and red light together.

Mr. HADDON remarked that the eye supplied the effect of the colour complementary to that actually falling upon it.

Mr. STARNES said he was much obliged to Mr. Debenham for demonstrating the truth of the remarks which he (Mr. Starnes) had made as to the use of an artificially-produced white light obtained by the superposition of coloured lights. Those remarks had been denounced by Mr. Lewis Wright and by the Editors of THE BRITISH JOURNAL OF PHOTOGRAPHY; but he was glad to see that their correctness was now fully demonstrated.

Mr. DEBENHAM was afraid he could not lay claim to Mr. Starnes's gratitude. As he understood it, Mr. Starnes proposed to convert rays of one colour and refrangibility into those of another colour and refrangibility. If two media could be employed, each of which transmitted one ray of the spectrum only, and this ray was not the same for each, the superposition of these media would produce darkness. All the available coloured media —at all events when used of moderate thickness—allowed rays to pass from some considerable portion of the spectrum. Thus the red and the green glasses he had been using both allowed yellow to pass, and therefore, if superposed, let yellow light through. The superposition of coloured lights upon a reflecting screen was, however, quite different from the superposition of coloured screens such as he had understood Mr. Starnes to advocate.

Mr. DEBENHAM inquired whether the Chairman had brought the lamp with diffraction grating (which, at the last meeting, had been stated to produce such a remarkable effect) for the purpose of test and demonstration.

The CHAIRMAN had not brought it, but would do so on a future occasion. Ultimately the 19th instant was fixed upon for the purpose.

Mr. STARNES replied that he had proposed the superposition of coloured lights, and had not mentioned that of either coloured glasses or other transmitting mediums.

It was announced that Mr. W. Coles's lecturette on *Altering the Density of Gelatine Negatives* would be given on the 12th instant.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE closing meeting for the session of 1883-4 was held in the Royal College of Science for Ireland, on Wednesday evening, the 21st ult,—Mr. Thomas A. Bewley in the chair.

Mr. HOWARD GRUBB, F.R.S., delivered a most interesting and instructive discourse on *Photographic Lenses*, in the course of which he described the nature of lenses in general and the way in which rays of light were refracted in their passage through them. He next touched on the many errors arising from spherical and chromatic aberration, astigmatism, &c., and the various means adopted for the correction of such errors in different types of lenses used in photography.

An animated discussion followed, in which the Chairman, Messrs. J. V. Robinson, H. Bewley, E. P. Johnson, G. Pim, and others took part.

Mr. R. C. WALKER showed a single "back" which he had constructed almost entirely of Willesden paper, and which was found to answer exceedingly well, being very light and portable.

The meeting was then adjourned to October next.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Society was held at the Free Library, on Thursday, the 29th ult.,—Dr. Kenyon, President, in the chair.

The minutes of the May meeting having been read and confirmed, Messrs. Cross, Heape, and Stott were elected members of the Association.

The Hon. Secretary read a letter from the Secretaries of the Associated Scientific Societies, and also the balance sheet of last year's *soirée*. With reference to the suggestions of the Committee contained in the letter,

Mr. J. H. T. ELLERBECK proposed and Mr. B. BOOTHROYD seconded a resolution that the Liverpool Amateur Photographic Association should repeat its guarantee of £5 towards the funds of the Associated *soirée*.

Some discussion ensued as to the proposals of Mr. Leslie for more extended action on the part of the Associated Scientific Societies of Liverpool.

Finally Mr. BOOTHROYD proposed and Mr. A. BEER seconded a resolution that the present delegates of the Association to the Associated Committee be re-elected, and that they be instructed to report further to the Society on the subject of Mr. Leslie's proposals.

Both the resolutions were assented to.

Mr. A. Beer exhibited and explained a new and very ingenious changing-box.

Mr. E. Roberts showed a fine negative developed by himself with—

Washing soda	1 ounce.
Bromide of potassium	3 grains.
Water	10 ounces.
Pyro.	10 grains.

This formula had been given in the present year's Almanac, and Mr. Roberts said he found it a capital developer, giving clean negatives of good printing colour and density.

The Chairman asked Mr. Roberts how this developer acted as regards fog.

Mr. J. H. Day remarked that an artist friend of his had used the soda developer exclusively for some time with the very best results, but he (Mr. Day) would like information as to rapidity of action.

Mr. Roberts said that he had only used this formula with some Swan's plates which he had kept by him for some two years, and with these plates he certainly found it slow; but possibly it would not differ from other developers in this respect when fresh plates were used. There was perfect freedom from fog.

Mr. Rogers and the Chairman exhibited specimens of Mr. George Smith's sciopticon camera. This little camera measures when folded $2\frac{3}{4} \times 5\frac{3}{8} \times 4\frac{3}{4}$, and weighs under $1\frac{1}{4}$ pound; yet it carries a $3\frac{1}{4}$-inch square plate, and has a range of focus of from $2\frac{1}{4}$ to 12 inches. The double dark slides are correspondingly light, and the whole work in the most simple and yet rigid manner; there is a rising front and a swing back. The great novelty is the manner in which the extra range of focus is provided for without detriment to the field of short-focus lenses, and in this respect the pattern is the very model of perfection. At last photographers have an apparatus so portable that it can be carried anywhere without fatigue, and yet of such range of power and rigidity that there is really no drawback in regard to efficiency. Mr. Smith's persevering efforts to introduce lightness without sacrifice of power into photographic apparatus have thus at last attained a complete success. A light stand is in course of preparation; meanwhile, the original scenograph with stand answers perfectly for mountain work.

The Chairman called attention to some good prints of portraits and groups taken by Mr. H. N. Atkins with one of Smith's cheap single lenses.

Mr. Watts read a paper, *On the Development of Instantaneous Pictures* [see page 359], and passed round a number of prints in illustration of his remarks.

The Chairman, in proposing a cordial vote of thanks to Mr. Watts for his careful and useful paper, remarked that the Society was much indebted to Mr. Watts for his paper and for the trouble he had taken in preparing negatives to illustrate it. He (the Chairman) had little doubt but that the principle enunciated by Mr. Watts was the correct one, and would in practice be found of substantial benefit. This was testified by the relative times occupied by the development of the negatives exhibited, and to some extent by the relative densities of the negatives; but, as to detail, it was noteworthy that the difference between the negatives exhibited in this respect was scarcely appreciable. This corresponded with the recorded experience as to different proportions of bromide in the developer, viz., that a large proportion of bromide, although it lengthened the period of development, produced no real loss of detail.

Mr. H. N. Atkins had, since the last meeting, been experimenting in the direction pointed out by Mr. Crowe in his valuable remarks at the April meeting, and found his formulæ work admirably.

Mr. Watts said that he thought it important to use sulphite of soda in fresh solution of pyro., and alluded to the tendency of sulphite to change to sulphate if the solutions were kept too long.

Mr. Crowe exhibited some specimens of his instantaneous work, taken in the streets of Liverpool on the Queen's birthday.

The Chairman explained a new apparatus by Lancaster, of Birmingham, for affixing a camera to a bicycle.

The meeting, which was numerously attended, was then adjourned to the last Thursday in June.

DERBY PHOTOGRAPHIC SOCIETY.

At a meeting held at Rodney-chambers, Corn Market, Derby, on Wednesday, the 28th ult., Mr. Arthur J. Cox occupying the chair, the Derby Photographic Society was formed for the promotion of the art.

About twenty members were enrolled, and the Society shows every prospect of being a most successful undertaking. Among those elected were Messrs. C. E. Abney, Richard Keene, Arthur J. Cox, H. Arnold Bemrose, J. E. Kaye, J. W. Price, and T. Scotton. Mr. Fred. W. Simpson, Hamilton Villas, Mill Hill, Derby, was elected Hon. Secretary.

The first meeting will be held this month, when a paper will be read on some photographic subject by a member of the Society, and will be followed by a discussion.

BOLTON PHOTOGRAPHIC SOCIETY.

The first outdoor meeting of the season was held on Saturday, the 24th ult., at Adlington, near Chorley. The weather was beautifully fine and clear, and caused a good muster of members to assemble. About twenty (including some friends) left Trinity-street station for Chorley, and thence walked on to Yarrow. As most of the members were fully armed for photographic warfare their appearance caused no little surprise to the natives, and in one or more instances the object of the strange party was rather energetically canvassed.

The woods behind Yarrow hotel proved fertile in "bits," and the members soon began operations. Modesty prevents us stating the number of plates exposed, but the manufacturers certainly had an "innings." Proceeding through the woods the party emerged on the banks of the canal above Adlington. Not "striking ile" a start was made for the Boltonian's elysium—Rivington. Plates were exposed on the house and beautiful grounds of the late Mr. Martin, and it was getting late in the evening when a *réunion* took place at the "Black Lad" for tea.

Thanks to the kindly forethought of Mr. R. Harwood, tea was soon served and fully appreciated. Great praise is indeed due to mine hostess for the liberality of her catering. After spending some time in strolling around the lakes a start was made for Horwich Station, and the party arrived in Bolton about nine o'clock. The trip was thoroughly enjoyed, and it is hoped that future outdoor meetings may be favoured with similar weather.

The next meeting is appointed to take place at New Brighton.

NORTH STAFFORDSHIRE PHOTOGRAPHIC ASSOCIATION.

A meeting of this Association was held on Wednesday, the 4th instant, at the Mechanics' Institute, Hanley,—Mr. C. Alfieri, Vice-President, in the chair.

Mr. R. S. Burgess exhibited two instantaneous shutters received from Mr. J. J. Atkinson, of Liverpool—the "Kirkby" and "Eclipse."

The Chairman exhibited two shutters of his own manufacture, both opening and closing in the centre, working behind the lenses, and forming at the same time the sliding-front of the camera, the weight of the whole being but a few ounces.

A shutter sent by Messrs. Reynolds and Branson was also exhibited.

It was unanimously agreed that, as the Society could work more harmoniously free from the professional element, with the exception of one gentleman, the names of the above be erased from the list of members, and that the Society henceforward be designated the "North Staffordshire Amateur Photographic Association," the following gentlemen constituting the committee:—Messrs. Emery, Alfieri, Burgess, Taylor, Insull, Kampton, and Kirkby.

It was resolved that an excursion be made on Wednesday, June 25th, to Alton and Froghall, per conveyance from Stoke-on-Trent, the members to assemble there, each to have the privilege of bringing a lady friend. It was also resolved to engage permanently a room at the Potteries Mechanics' Institute, Hanley, for purposes of holding meetings, giving demonstrations, &c.

After some interesting conversation and discussion upon various photographic topics the meeting was terminated.

BERLIN ASSOCIATION FOR THE CULTIVATION OF PHOTOGRAPHY.

This Society met on the 21st March,—Professor H. W. Vogel in the chair. Several new members were admitted.

A letter from Paris was then read, in which Herr Trant described Klary's method of colouring photographs, so as to make them look like water-colour drawings, and a new retouching pencil by Faber.

Herr V. Kolkow inquired what was the best sort of glass for the roof of a glass-house, and several of the members present recounted their experiences with different sorts of glass. He (Herr Kolkow) then mentioned that some Westendorp gelatine plates, which had been taken on a North-Pole expedition, and had been subjected to a temperature of 30°, had behaved very well; but, unfortunately, most of them appeared over-exposed.

Herr Tschentscher sent some cuff-studs ornamented with photographic portraits, the preparation of which he makes a speciality. The picture side of the photograph is coated with gelatine and affixed to the back of a round glass, and then the whole fixed by *adamantine cement* to a stud back. Herr Tschentscher complained that the photographs generally soon turned yellow, and inquired whether that might be caused by the gelatine or the cement?

No one being acquainted with the cement named, it was not possible to say anything positive on that point; but one of the front plates which was pulled off from the stud part was pronounced to have an acid taste, and the probability is that acid in the cement was the cause of the yellowing. It was said that many of the cements sold under various names consist mainly of gelatine and acetic acid.

Herr Christmann remarked that pictures mounted with gelatine upon glass yellow more rapidly than those mounted in the usual way—perhaps owing to the acid in the gelatine.

The programme of the Photographic Society of Great Britain was then discussed, particular attention being given to the standard stops. Some members approved of the idea, while others considered it impracticable and the gradations not gradual enough.

Herr Graf showed some *plaque* portraits and an embossing-press. The portraits were much admired; but it was suggested that they wanted some protection from air and dust, either in the form of a glazed frame or of a coat of varnish.

Herr Kurtze exhibited a large collection of landscapes and architectural views.

The Chairman gave an account of his experiments towards giving the true optical value of colours to photographic reproductions of pictures. He showed a photograph of a colour scale taken by the old method, and the same by a newer method. The difference between them was very striking. Chrome yellow, yellow ochre, and Schweinfurt's green all appeared lighter than ultramarine blue. Red lead and vermilion were both lighter than formerly. Alizarine, on the other hand, by the new method of staining films, is darker than formerly.

The short lecture was listened to with great interest, and at its conclusion the meeting was adjourned.

Correspondence.

ALBUMENISED PAPER.

To the EDITORS.

GENTLEMEN,—For some time past I have used almost exclusively the ready-sensitised paper now so common. This, though undoubtedly convenient and possessing some advantages, has also disadvantages, which make me desirous of giving it up.

But I find, nowadays, that I cannot sensitise my own paper to give results at all approaching those I obtain on the ready-sensitised, nor even equal to those I once obtained with ease. Comparing some of my pictures, produced before the days of ready-sensitised papers, I can but sigh and wish that I could equal them now.

What is the reason of this falling off? I am myself convinced that it is in the papers supplied at the present time (I have tried most of them of good repute, with similar results), for only a few weeks ago I accidentally came across a-quarter sheet of albumenised paper that must have been in my possession at least twelve years, and upon trying it, as a matter of curiosity, I was surprised and struck with the marked difference in its behaviour as compared with modern samples. Not only was the quality of the prints better than I am now accustomed to, but the results were got without any trouble or "nursing" in the toning and fixing.

If, as I believe, the modern paper is at fault, cannot something be done to induce paper makers or albumenisers to revert to their old methods? If it is merely a matter of using pure albumen, stronger salting, a more carefully-sized paper, or anything else that adds to its cost, then I for one would gladly pay twice, thrice, or ten times the extra cost to get a good article. Albumenising is not an operation that can be performed on a small scale, or I would be independent of commercially albumenised paper.

Is there anything that can be done to improve the quality of the prints obtained upon a weakly-salted or albumenised, but otherwise good, paper? The makers of the ready sensitised article appear to have some such secret. —I am, yours, &c., A. E. P.

London, June 4, 1884.

IMPROVEMENTS AND DISCOVERIES.

To the EDITORS.

GENTLEMEN,—Under the heading of "A Correction," Mr. A. Mackie gives the credit of the discovery of water in the place of air for the releasing of catches attached to photographic shutters to Mr. Sands. This I believe to be incorrect, as our esteemed Hon. Secretary of the Manchester Photographic Society, Mr. W. J. Chadwick, patented that and other fluids and semi-fluids.

In the same article which called forth Mr. Mackie's remarks there is an allusion to a *new* mechanical arrangement for releasing catches patented by Mr. Warnerke. This I have had attached to my camera for the last three years, and others I have made for members of our Society. This is another of the instances in which two minds arrive at the same result, and which the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY have been so familiar with during the past few years. The one I have attached at present I believe is a decided improvement on Mr. Warnerke's, as instead of the motion being a push it is a pull, which enables it to be attached to a flap shutter for the purpose of keeping it open for a longer or shorter period, similar to Cadett's pneumatic flap. The inner coil of wire I make upon a knitting needle running in the lathe, afterwards covering it with Maw's black india-rubber tubing used for feeding bottles. For the inner wire I substitute catgut, which I find far preferable to any metallic motor, as it is not liable to become bent and gives more elasticity to the arrangement when finished.

I shall have great pleasure in sending you a camera to which it is attached for your inspection, if you think it would be of any service.—I am, yours, &c.,

Victoria Cottage, Vernon Grove, Eccles, Manchester, May 31, 1884. W. BROUGHTON.

[It will afford us pleasure to examine the camera.—EDS.]

THE REGISTERING LANTERN CARRIER.

To the EDITORS.

GENTLEMEN,—Our Mr. William Chadwick thinks your article on *Lantern Industries* in this week's journal reads somewhat as though Messrs. Oakley were the original inventors (or proprietors) of the registering lantern carrier.

Mr. William Chadwick, Mr. Arthur Coventry, and the late Mr. Michael Noton used a carrier of this description, for a single size slide, seventeen or eighteen years ago—thus five or six years before Oakley's commenced business.

The carriers for registering the various size of slides is undoubtedly the original invention of Mr. Chadwick, and those made by him were perfect pieces of apparatus, although the imitations made by other firms were far from being so. (See his contribution to THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC in 1878).—I am, yours, &c., R. H.

Liverpool, May 30, 1884.

[The first registering carrier for lantern slides of which we have any account is that described in the issue of THE BRITISH JOURNAL OF PHOTOGRAPHY for January 10, 1868, in an article by the then Editor, entitled *Transparencies: How to Mount and How to Exhibit Them*, in the course of which our predecessor says:—"The method we are now about to advocate is one that we designed many years ago, and have had in constant use ever since. There is no person to whom we have shown or recommended it who has not been pleased with its efficiency and simplicity. It consists of an adapter, which is placed in the lantern and allowed to remain there." And then follows a detailed account, illustrated by a drawing, and giving all the necessary measurements for constructing the adapter that is in general use at the present day for exhibiting slides of one standard size.—EDS.]

CHANGING PLATES.

To the EDITORS.

GENTLEMEN,—The following may be useful to some reader:—A year ago I had a changing-box made of light American wood and the size of camera I use for whole plates. When out for a day the box holds camera, plates, &c. That makes only one box to carry.

The sleeves I got made of brown leather, which is much better than any textile fabric. I have used the same box lately for changing plates (quarter size) in the studio, and find it much more pleasant for the eyes than shutting myself in the room to change plates, and rush out in the glare of the glass-house. (Take note who wants to take care of the eyes.)

There is nothing easier than changing plates by *feeling* in the box. I read of someone who tried their blankets for a changing-bag! This is better. I changed twenty-two quarter-plates the other day, using my waterproof coat for a bag. Button up the front and lay the coat flat down, keeping the back up; fold in below the lower part so that it may be close and tight; insert the dark slide at the neck opening, and fold under the same; hands in through the sleeves, and see it is close, and you can change plates without any light getting on them if your coat be really waterproof. Try it if you ever leave your changing-box behind and find yourself in a "fix;" though that was not the case with,—Yours, &c.,

Lerwick, Shetland, May 28, 1884. C. SPENCE.

Notes and Queries.

GEORGE BAXTER inquires:—"What will be the effect if I place a piece of pale green glass in front of the lens when I take a landscape?"——In reply to this we inquire, in return—"Why not try the experiment, and let us know the result?"

HENRY MARTIN inquires what has been the final outcome of the addition of iodide of mercury to the developing solution, as recommended by Mr. Henry J. Newton, of New York.——We reply to this by saying that we do not know. In the hands of ourselves and a few friends it was not found to produce the effects indicated.

URANUS.—This correspondent desires to have our opinion on a solution of iodine in ammonia as a detergent in the case of several very bad silver stains on his hands.——It is certainly a desperate remedy, but still it *is* a remedy, for the evil of which "Uranus" complains. All we would say is this:—See that the iodine is always largely in excess, and then no danger will accrue.

B. F. says he has tried a method of mounting prints recommended on the authority of Mr. A. Cowan and others, but without success. He applied starch to the backs of the prints and also to the face of the mounting-board, and allowed both to become dry. He then passed a damp sponge over the surface of the mount, and, laying a print down upon it, pressed them in close contact; but, after allowing a reasonable time for them to become dry, he found that they were not attached at all.——We have no doubt the failure in this case arose from the pressure having been altogether insufficient to bring the print into the requisite close contact with the mount. We can testify to the efficacy of the system when properly worked with the degree of pressure necessary to its being effectively done.

BATCHELDER AND CO. (Melbourne).—Our correspondents inform us of an invention made and perfected by an amateur in New Zealand, by which any amount of angle of view can be included. It differs in construction from the pantascopic camera, or from any other previously described. A print measuring 24 × 5 inches and embracing an angle of 140° has been seen by our correspondents, who inquire if such an apparatus would be likely to "take" in this country. This is a matter upon which we have great diffidence in offering advice. At various times in the course of the past thirty years panoramic cameras have been introduced, some of which have been most effective, and yet none of them have, so far as we can learn, been commercially successful. We shall be glad to put any maker desirous of taking it up in communication with our correspondents at the Antipodes.

PHOTOTYPER would like to be informed of a method by which collodion negatives from engravings could be rendered very intense, so as to stand severe printing in a strong light without the whites becoming affected. ——Answer: There are two among many other methods of intensification by either of which he will attain the desired end. The first consists in bleaching the negative, after being fixed and washed, by the application of a solution of bichromate of potash to which have been added a few drops of hydrochloric acid. After the deposit has become quite white wash carefully, and apply a ten-grain solution of Schlippe's salt, by which the image will be made of a dense brown colour. By the other method the negative, after fixing and washing, is bleached by a solution of bromide of copper, followed, after being washed, by a solution of nitrate of silver. This gives great opacity to the deposit. If any difficulty in procuring the bromide of copper be experienced it may be readily made by dissolving nearly equal parts of bromide of potassium and sulphate of copper in different vessels and mixing them together. Nicety of proportions is not required in this case, nor does the presence of the sulphate of potash interfere with its working.

W. D. R. has an accumulation of gelatine plates that he has made at various times for experimental purposes, some of them being very rich in silver. He inquires if there be any ready method by which he can recover this silver, which, in his estimation, must amount to many ounces.——In reply: Let him immerse them in a fixing bath and then recover the silver in the form of sulphide, in the usual way.

REV. BENJ. F. STODARE.—Our correspondent has become the possessor of a fine engraving by Goupil, executed by the Rousillon process, and he inquires if we can afford him some information concerning the process of engraving employed.——So far as we know the Rousillon process is similar to one by Mr. W. B. Woodbury, who invented it and introduced it sufficiently to enable any skilled workman to carry it into practical effect. The Rousillon method may, however, be quite different. Being worked as a secret process we have no means of pronouncing upon it; but we are at one with our correspondent regarding the admirable results obtained by its agency.

Exchange Column.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

NOTICE.—*Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a* NOM DE PLUME *as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.*

PHOTOGRAPHS REGISTERED.—

Thomas Riley, 52, Manchester-road, Burnley.—*Two Photographs of the Laying of the Foundation Stone of Victoria Hospital for Burnley and District.*

W. LANG, JUN.—*Anal. Zeitschr.*, 23, 33-35.

J. KNOWLES.—Sealing-wax varnish—such as that used for electrical machines—is simply ordinary red sealing-wax dissolved in methylated spirit.

PYRO.—There is no satisfactory way of making enlargements direct on canvas. The powder or the carbon process is the best we know of for such pictures.

O. P. S.—From the description given of the instrument we believe it to be an orthographic lens; but without seeing it we could not pronounce definitely with respect to its capabilities.

A. S. FERGUSON.—There is nothing at all extraordinary in the first washing water of your prints having a strongly acid reaction to litmus paper. Most ready-sensitised papers are strongly acid.

BENJAMIN.—The affair is more of a toy than a really serviceable photographic apparatus. So far as we are aware it is not now an article of commerce, for we have not seen one for several years, except in an auction room.

A. T. PENFOLD.—Do not send the kaolin itself to the refiner, but wash it in two or three changes of water containing a little nitric acid. Add this water to the washing waters from the prints; then the silver will be precipitated as chloride when the salt is added.

W. J. S.—The spots are doubtless caused by metallic particles detached from the "gold-edged" cards upon which the prints are mounted. Pure gold leaf would have no effect on the prints should any small particles get detached and come in contact with the photograph.

ARGOL.—Your chief fault appears to be in the employment of a too high temperature in emulsifying. The variations in the formulæ would produce no such effects. It is also possible that you are employing too small a quantity of gelatine in the earlier stage of the process.

T. B. (Liverpool).—Your query should be put to a respectable solicitor. We cannot undertake to answer questions on purely legal matters. From your statement we should surmise that you have good cause of action, and morally you should succeed. Consult a solicitor without delay.

L. H. W.—Two thicknesses of the orange paper enclosed will answer quite well for the window of a dark room where only collodion plates are manipulated. We fear, however, the colour will not prove very permanent. Keep a watch upon it, and make a change as soon as the outside sheet shows signs of fading.

J. S. R.—Without actually trying the paper it is impossible to give an opinion as to whether it will yield purple tones. You must bear in mind that rich purple tones in prints depend nearly as much upon the character of the negative as upon the paper. If the negative be unsuitable it is impossible to get purple tones on any paper.

THOS. BENTON.—Your failure, we should say, is due to your employing a sample of gelatine that contained alum, or, possibly, it was acid. In all processes dependent upon the solubility of bichromated gelatine a very pure sample of gelatine is imperative. That which you have employed is, we know, very unsuitable for such purposes.

C. WATSON.—Yes; mix the two kinds of residue together before you send them. We advise you, after mixing, to make the residue thoroughly dry, pound it in a mortar, and then pass it through a sieve. By this means you will reduce it in bulk and remove all extraneous matter, and so assist the refiner, enabling him to make a smaller charge for reducing.

ALPHA.—The reason your collodion turned quite red as soon as the iodide was added is that the ether was in fault. You say you have had it in stock for "two or three years," and that the bottle it was kept in was only half full. The ether being at fault is further proved by the rancid smell you say it has. We fear you will not now succeed in making it a good working collodion, although you may be able to render it colourless.

E. A. COULES.—Your failure, in making a solution of india-rubber, is twofold:—In the first place: you have used benzoline, in which rubber is not soluble, instead of benzole, in which it is. In the second place: you have employed vulcanised rubber, and that is insoluble, even in benzole. Try again, using benzole and good bottle rubber. If you can get "masticated" rubber in your neighbourhood it is the best kind to employ, as it will dissolve more readily.

LEX.—We have always succeeded very well with the ozone bleach. Perhaps with more experience you will succeed better. The best plan of reducing by abrasion is that of Mr. Barber, who recommends the film to be gently rubbed with cuttle-fish powder. In our hands the former plan is the more satisfactory. Messrs. Hopkin and Williams will supply the chemicals in a state of the greatest purity. The foreign pyrogallic acid named by you is of very good quality indeed; so is the English manufactured by the above firm.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 11th inst., the subject for discussion will be—*On the Best Methods of Preserving Sensitised Paper*. Saturday afternoon meeting at Hampstead Heath, North End, and West Heath. Members will meet at the Bull and Bush, at 6.30.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next ordinary meeting of this Society will take place on Tuesday next, the 10th inst., at eight p.m., at 5A, Pall Mall East, in the Gallery of the Royal Society of Painters in Water Colours, when the discussion upon Mr. W. E. Debenham's paper, read at the last meeting, will be taken. Papers will also be read on *Commercial Fabrics Suitable for Dark Room Illumination*, by Mr. J. R. Sawyer, and on *Silver Prints*, by Mr. E. Dunmore.

BALLOON ASCENT.—We are favoured with the following from Mr. Cecil V. Shadbolt: — "The first ascent of our new balloon (at present without any name) took place, on Saturday afternoon last, from the Crystal Palace, at about 5.20, when we had a most enjoyable trip. The little machine fully realised all expectations and lifted three persons easily. There were in the car General Brine, Mr. Dale, and myself, and the ascent was a very steady one. We did not go much beyond 2,000 feet high, and when over Croydon at that altitude a pigeon was let loose, which reached its home at Chislehurst about two hours later. Another despatched five minutes after the first did not get in until after dark. The descent was effected at Woodcote Grove, Wallington, Surrey, on the estate of Mr. Puckle, who, with his son, accorded us a hearty and courteous reception, and, after having entertained us at his house, kindly placed his wagonette at our disposal, in which we drove to the station, the balloon having previously been sent on by a cart, also belonging to our host."

CONTENTS.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1258. Vol. XXXI.—JUNE 13, 1884.

THE PHOTOGRAPHIC SOCIETY.

We should not have noticed a matter which somewhat affects us, had it not been that the correspondence published in another column (a portion only of what we have received) proves that the letter to which reference is there made has already produced an impression—so far, we are glad to say as it affects us, favourable to our side. The charges, if we can so call them, are also by this time in the hands of every member of the Photographic Society of Great Britain, a very large percentage of whom are country members who, beyond the Society's *Journal*, have no means of gauging either the opinions of their fellow-members or the correctness or otherwise of the reports of its meetings.

In order, then, to prevent any misapprehension on the part of non-resident members we shall make a few explanatory remarks; and, as many of our own readers are not members of the Society, we append Mr. Herbert B. Berkeley's letter in full, which appeared in the last number of the Parent Society's *Journal*, in order that they may be able to judge the value of his complaint:—

29, *Southampton-row, W.C., May 3rd.*

To the Editor.

Sir,—Would it not be well to revive a former custom of sending out slips for the correction of members who have spoken at the meetings, whether general or technical?

Errors and omissions are of frequent occurrence in this Journal, and not only in the reports of *other* journals, where, under the present system of publication of a non-official character, such errors must remain inevitable. By the way, I fail to see any logic in the conclusion that, were the publication of the reports of meetings now contained in the weekly photographic press delayed until the full and corrected (presumably) report could be taken from this Journal, such publication would form "stale news." As well might we say that the papers so delayed in publication are "stale news." I take it, correctly speaking, that the paper read requires publication rather *before* the remarks made upon it than after them. Hence, delay in the publication of the discussions arising upon papers should be an advantage of some importance. Properly, one and the same issue should contain both paper and the discussion upon it.

But the best argument of all must be that at present the reports in the weekly press are meagre and incorrect; while, I admit, that those in this Journal might be improved upon by adhering to the practice of sending out slips for correction.*

Again, in any case, what is the use of "fresh news" if it is not to be depended upon as correct?

I should suppose that many who are readers of the photographic press must be of much the same opinion as myself upon these matters.—I am, sir, yours faithfully, Herbert B. Berkeley.

So far as concerns the management of the Society's *Journal* and the sending out of slips we have nothing to do, and shall confine ourselves to the portion of the letter which affects the "weekly journals," premising that under the "present system of reporting," whether official or "unofficial," or, indeed, under any system whatever, it is perhaps inevitable that errors must remain—at least in the opinions of some. If the condensation of a speaker's remarks while still retaining his *sense* constitute error, the whole science of reporting is vicious; if, on the other hand, the careful elaboration, extension, and final polishing of a speech until it represents what the speaker himself thinks he intended or ought to have said be the ideal of correctness, then a new style of journalism must arise before the system can secure adoption. "Weekly" or "commercial" journals, whether photographic or otherwise, have too many calls on their space to permit them to be run in the interest of any one society. Their object is to work for the benefit of the greatest number, and their success is commensurate with the manner in which they carry out the attempt. Mr. Berkeley can scarcely charge us with any want of attention in this respect to the society to which he belongs, reports of whose meetings occupy at least as much space and, we venture to say, are quite as accurate as those of any of the numerous other societies whose proceedings we record.

Turning to the suggestion of the delay of our reports until the publication of the official corrected reports, we can only say that it was waste of time to mention it. If the weekly journals consented to this course, which they are not likely to do, they would be sadly wanting in their duty—not only to photography and photographers generally, but especially to the members themselves—if they kept back any account of the proceedings of the Society until such time as they were able to cut it bodily from the official *Transactions*, in which every member would already have had an opportunity of seeing it; and this because a few members hold the idea that the Society should have a sort of copyright in its proceedings.

Considering that the Photographic Society of Great Britain is supposed to be the representative national society, it owes it to British photographers and the world that its proceedings be as promptly and as widely circulated as possible, instead of being nursed for a month, and finally given to the world in a private journal which scarcely circulates beyond the members of the Society.

On the question of accuracy in reporting the speaker himself is not, perhaps, the best judge; and where the reporters employed are practical men—that is to say, not only reporters for the nonce, but practical photographers—they may well be entrusted with the task of condensing the sense of a speech within the bounds necessary in a weekly publication. This task is, we make no hesitation in saying, carefully and admirably performed in the "weekly journals," and fully as great accuracy obtained as by the system of permitting each speaker to elaborate and modify the remarks he may have made.

The "stale news" question would be settled simply and at once by the publication "in one and the same issue of both paper and the discussion upon it," which Mr. Berkeley recognises as the proper method. This can only be done when the Parent Society consents to place itself in the same position as every other Society in the United Kingdom, by allowing the weekly journals to have access to the papers read in time to be printed the same week they are delivered. The possibility exists if the will were there; but at present we fear we can see no probability of improving the "meagreness" of our reports—so far, at least, as the publication of the papers is concerned.

* Since writing the foregoing letter, I have been informed that the slips are still sent out for the corrections of members who have spoken at the meetings of the Society—I presume whether general or technical. I can only say that I have not received such after the more recent occasions on which I have made a remark; and that certain errors I have observed in the reports, from time to time, lead me to infer that my statement was correct. I also had further reason for my belief, into which it will not be necessary to enter. It may be, then, that slips do not always reach the hands of (or are mislaid by) the members to whom they are sent.

As regards their accuracy we are content to leave the majority to decide.

In conclusion: it is worthy of note that in the present number we publish simultaneously the report of the June meeting of the Society and the papers read at the May meeting—a fact which speaks for itself.

ON ALBUMENISING PAPER.

Complaints still continue to reach us from correspondents stating that it is now impossible to obtain the rich tones in silver prints formerly produced. The cause of this difficulty is usually ascribed to the use of the "ready-sensitised paper," together with negatives of a totally unsuitable character to produce such tones. However, as some of our correspondents write, this is not all; for if, instead of employing the ready-sensitised paper, they take the albumenised paper now in the market and sensitise it for themselves (using the strength of bath as recommended by the makers) the same difficulty still exists in securing the deep purple tones of former times, even if the identical negatives of old be employed. In a word, it is asserted that from the same negative it is now impossible to obtain prints of similar tones to others still in existence produced years ago on paper then an article of commerce. With this experience before them, it is by no means surprising that many should conceive the idea that the albumenised paper of the present day is prepared differently from what it used to be, or that the paper itself may be of a different character.

A letter from a correspondent which appeared in our last issue is a fair type of a very large number we have received during the past year or two, with, perhaps, one exception. Our correspondent says he accidentally found a piece of albumenised paper prepared some dozen years or so back, and curiosity induced him to sensitise and print it. The difference he found between its behaviour and that of any he can now procure was very marked indeed. He, therefore, not unnaturally inquires why manufacturers will not supply the same kind of paper at the present time. There is no question whatever that the albumenised paper of commerce *is* of a different character from that of a previous period, and the discrepancy has more than once been explained in our columns during the past few months. But this difference, it should at the same time be remarked, has been brought about, to a large extent, by photographers themselves. They have demanded a paper with the highest possible gloss. They also required a paper which could be weakly sensitised, as that kind of paper is found to suit better the general class of negatives now taken; and, furthermore, taste has changed, and warm, reddish-brown tones have become the prevailing fashion for photographs in place of purple.

Now, the first of these conditions, as we have before stated (see page 274 of the current volume), is directly opposed to the production of deep purple or black tones, inasmuch as the image is confined almost entirely to the albumen coating; whereas, for dark tones, it is necessary that it should, to some extent, be in the body of the paper itself. The second condition has necessitated that the albumen should contain but little chloride.

It is tolerably well known among practical printers that little or no advantage is gained with a weakly-salted paper by increasing the strength of the silver bath beyond a certain point, as no larger proportion of chloride of silver can be formed by so doing; therefore it is of little use, as many have discovered, employing a strong sensitising solution if the albumen contain but a small proportion of chloride. As the matter now stands, it would appear that if paper of the old character be required, capable of yielding a deep tone from suitable negatives, the only way of obtaining it is perforce to prepare it for oneself or to get it prepared specially. The latter is easily done if a ream or two be ordered, but few albumenisers would undertake to prepare a quire or two specially, or such small supplies as would satisfy the requirements of the amateur.

The preparation of albumenised paper, it may be mentioned, is by no means a difficult operation, though up to the present time very few working details have been published on the subject. It is for this reason, perhaps, that it is generally assumed the albumenising of paper is a somewhat formidable undertaking. However, it is not so in reality, and we shall here give such practical information on the subject as will enable any one, with a little practice, to prepare exactly what he requires.

The first thing for consideration is the selection of the paper itself. Of this, unfortunately, there is but little choice; for, practically, there are but three suitable for photographic purposes from which to select. These are the Saxe and the Rives. Of the latter there are two manufactories, but between the two there is little to choose in point of quality, though one is a trifle lower in price than the other. Formerly there was a considerable difference between the characters of the Saxe and Rives paper, but of late years this difference has been less marked. Each manufacturer appears to have emulated the best qualities of the other, and so the features of the two papers have become more assimilated. Still there is a difference, and it is very much a matter of taste as to which is to be preferred. It may, however, be mentioned that the Saxe is a tougher paper when wet, and for this reason is often preferred for large sizes. Each kind is supplied of different thicknesses. That more generally used is known as "ten kilos"—equal in weight to about twenty-two pounds per ream.

The paper being decided upon, the next consideration is the chloride to be used for salting it, and its proportion. The chlorides usually employed are those of ammonium, barium, or sodium—some preferring one and some the others, and some a mixture of two or of all three. It is said that the base of the chloride used influences the colour of the print; but this, in practice, is more imaginary than real—that is, in the finished print, though there may be a difference in the colour when it is first taken from the printing-frame. However, owing to the difference in the atomic weights of the salts, the proportion used is a matter of great importance, inasmuch as ten grains of the ammonium chloride is equal in the amount of chlorine it contains to eleven grains of sodium chloride, or twenty-two of the barium salt. The salt generally employed, and the one we prefer ourselves, is the chloride of ammonium. With regard to the proportion: that must be dependent upon the strength of sensitising bath to be employed. Bear in mind that the more strongly the paper is sensitised, all things being equal, the stronger will be the resulting print; for the more reduced silver it contains the greater will be the ease with which dark tones can be obtained when required.

It has been found in practice that, as a rule, the best results are obtained, so far as the print is concerned, when, supposing the chloride of ammonium to have been used, the proportion of chloride in the albumen equals in weight one-eighth of the nitrate of silver employed in the sensitising bath. Thus, if a forty-grain bath be used, the albumen should contain five grains of chloride to each ounce; but considerably less than this, we are informed, is often employed, and there are still weaker baths than that mentioned. For a sixty-grain bath seven and a-half grains is found to be about the correct proportion. When it was customary to salt the paper as highly as ten or twelve grains to the ounce of albumen, baths of from eighty to one hundred grains' strength were in vogue.

With these preliminary notes we shall defer until next week the consideration of the practical portion of the question.

FOCUSSING-SCREENS.

In a previous article we have spoken of the twofold function of the focussing-screen as a means of securing a sharp focus, and also of seeing the composition of, and arranging, the subject to be photographed. Bearing in mind what has been said concerning the value of a compound microscope for securing a sharp focus upon a plate of plain glass, and the difficulty of doing so upon a ground-glass surface, there are certain compromises between the two that suggest themselves in addition to those of which we have already spoken.

A surface rendered granular by means of what is so well known as ground-glass varnish answers well for one purpose—namely, the examination of the subject—but not for the other. Still, this method of preparing a focussing-screen is useful when a magnifier such as that which we advocate is employed; for it is easy by means of benzole to clear off a small spot in the centre of the screen against which to place the pocket focussing tube. This is a method we have tried with complete success, the ground-glass varnish employed for the purpose having been composed according to the standard formula published at page 229 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the current year. But, as we have observed, this forms a bad surface upon which to focus with any degree of refinement or certainty, because of the particular nature of the matt formed by the action of the two antagonistic solvents of the gums, benzole and ether.

When glass is coated with a thin solution of starch and allowed to become dry, a surface is secured which possesses certain advantages over all others. It possesses a very fine grain—one which, better than any other, is adapted for arresting the rays from the lens under circumstances conducive to the examination of the image either by a single powerful magnifying glass or by the compound tube. The objection to the employment of a single or simple magnifier, even if it be composed of a doublet or triplet, is this—that when used in conjunction with a plain glass focussing-screen there is a certain degree of latitude in the determination of the precise plane upon which the virtual image is projected—a latitude that does not exist when the rays are arrested by any image-receiving surface on the one hand, or, as already explained, by any polished surface on the other, when used in conjunction with a compound magnifier.

An etherial solution of wax has sometimes been recommended as a coating upon which to receive an image. In such experiments as we have made with this substance the result, although exceedingly pleasing when employed as a backing for a transparency, is not successful when used as a focussing-screen. Much better is a film of collodion modified in its physical structure by the admixture with it of an alcoholic solution of lac or the other gum resins which form the solid constituents of a good negative varnish. It is, doubtless, known to many of our readers that if collodion and negative varnish be mixed in certain proportions—the precise nature of which could not be stated unless the exact constituents of each were known—a varnish results which, when applied to a glass plate, dries with an appearance possessing singular beauty. Although both constituents are in themselves transparent, and give transparent films when used separately, yet when mixed the film given by their union is neither opaque or transparent, but it possesses a remarkably-beautiful opalescence.

This, although pleasing and useful as a backing for transparencies, is still of too purely an opalescent character to render it useful for receiving or arresting an image. It gives a surface too nearly conforming to that of opal glass to be of any utility as a focussing-screen. This also applies in some measure, although not to such an extent, to the employment of a bromo-iodised, collodionised plate which, having been immersed in a silver bath, is afterwards charged with atoms of reduced silver through the intervention of a developing solution, these silver particles being exceedingly fine. In this category, too, may fittingly be included emulsions composed of such amorphous salts as sulphate of barytes suspended in either collodion or gelatine.

We may here observe that this last-named preparation forms an admirable backing for transparencies, especially for those which are intended to be viewed through powerful magnifying glasses. The best way of forming the barium sulphate is by adding a little sulphate of soda to a solution of gelatine, and afterwards a solution of chloride of barium. If this be done well, with constant agitation, the resulting sulphate of barytes is very fine and evenly distributed throughout the entire substance of the gelatine.

If, by accident, a focussing-screen has been broken when the photographer is at a distance from any point of supply, the best substitute he can adopt is starch, which, happily, is procurable everywhere. To apply this substance to plain glass all that is requisite is to level the plate, and, having previously boiled and strained the starch, to pour it upon the glass, allowing it to remain quite level until by the evaporation of the water the film becomes hard and dry.

There are some photographers who adjust the subject to be photographed by sights placed on the top of the camera. This is an excellent system, especially when photographing at a distance from home. We have no hesitation in saying that the cameras of every traveller should have such sights affixed to them in case of accident to the ground glass.

Further: to permit of sharp focussing when such accident happens, it would be well to have provided a small but rigid strip of wood capable of being laid across the frame of the focussing-screen, and carrying in its centre a magnifier adjusted in such a manner as to enable a sharp image to be received in air when there is no ground glass at all to intercept it. This air image must, of course, be made to correspond in position with that which falls upon the surface of the sensitive plate. For such a purpose the magnifier, when once adjusted, must be rigidly fixed so as to be incapable of alteration. This will render the photographer entirely independent of the ground focussing-screen should it by accident become destroyed.

DECOMPOSED ALBUMEN: ITS EFFECTS UPON PRINTS.

WE have had shown to us some albumenised paper prints the appearance presented by which caused a complaint to be made that "the paper was defective and decomposed, having a very strong smell to start with, and before the prints were finished washing that caused them to go bad and turn a sickly-brownish green colour." This case forms such an instructive rider to our recent remarks upon the all-important question of permanency that it may be worth while to watch the passage of a print through all its stages to see where faults could arise, and to understand their cause.

We naturally turn first to the examination of the albumenised paper, with regard to which it is a common experience that the market is nowadays flooded with foul-smelling samples, whose very presence in a room is in the highest degree obnoxious. It is matter of surprise to us that the printers who employ it do not suffer in health, the odour of even a spacious and well-ventilated room where it is employed in quantity being most offensive to the olfactory nerves, and, it might be thought, productive of certain injury to those who were long subjected to its effects. The cause of this smell may be traced to the combined influence of cheap prices and that demand for a highly-glazed surface in the production of which manufacturers are continually endeavouring to excel each other. In the first place, other than egg albumen is employed; and, in the next, when such albumen is used it is allowed to become putrid, in order to permit of its more easy flow.

When albumenised paper first came to be employed a very slight gloss only was given, and such samples as are now to be seen were then unknown; but, as the demand for portraiture grew, it was quickly discovered that greater richness was given the greater the amount of surface gloss. Foul-smelling paper was at that time unknown; but the difficulties of getting a brilliant surface were so great that, when it was discovered that by keeping the albumen till putridity was developed it became much more limpid, and the paper in consequence more readily coated, this method of treating the albumen became very common, though there were many honourable exceptions in a trade which, even at that early date, had already begun to assume large proportions. The paper, however, coated by egg albumen that had undergone partial decomposition did not possess the extreme offensiveness common to so many kinds at the present day. When coated and dried it was certainly mal-odorous as compared with that made with fresh albumen, which, practically, was without smell at all; but the odour was very different in character, and not nearly so powerful nor so nauseous.

This increased offensiveness we believe to be owing to the employment of blood albumen—which is apparently similar in composition to egg albumen, and is now produced in very large quantities—but it is difficult to purify, and we should have a decided prejudice against its employment. It is, however, cheaper, so that a highly-glazed paper can be sent into the market at a price which would render competition almost impossible with paper coated in an orthodox manner and with pure fresh egg albumen. A paper put upon the market many years ago—which was readily distinguishable by its smell, but which had by no means a particularly bright surface—

was one of the earliest samples we have seen of impure papers. It was one of the easiest to tone, and, further, gave a very rich colour; it also worked pleasantly and easily all through.

It is evident, now, that more causes than one contribute to create the smell of the offensive class of paper, and the only question to consider is—Which, if any, causes, or is likely to cause, fading? Nitrate of silver is so readily reduced by many organic compounds that if its decomposition took place upon the paper by reason of their presence in any form, volatile or fixed, we might have a legitimate expectation of seeing visible witness of their existence by staining of the paper; and from the absence of such stain the inference might be fairly drawn that compounds capable of decomposing the silver were also absent. It goes without saying that some of these objectionable papers are quite capable of holding their own against those of undoubted purity when the question of purity of whites is concerned.

There is, however, one constituent of albumen, namely, sulphur, which all photographers have been taught to look upon with suspicion, and it is this element which predominates in the gas given off by decomposing albumen. But it is also to be remembered that the sulphur exists in the albumen before it decomposes, and it is a fair question to ask—What grounds exist for supposing the sulphur, when separated into what must unquestionably be a simpler form of combination—the unpleasant smelling gas—to be more liable to decompose silver compounds than in its first state, when it is combined with other elements to form egg albumen? Logical deduction really would point to an exactly opposite conclusion, namely, that the more simple compound would be the less easily decomposed, and we all know how readily sulphur can be separated from egg albumen. The appearance of a silver spoon which has been used with a boiled egg is convincing proof.

It is highly probable that whenever albumenised paper is silvered, however pure may have the albumen employed, a sulphur compound is formed; and, indeed, Mr. John Spiller showed years ago that unless ammonia were used with the hypo. there always remained silver in the purest-looking whites of every fixed print.

All argument, therefore, goes to show that the employment of decomposed albumen is not more likely to produce fading in albumenised paper prints than is pure albumen. Experience, again, is here the best, and indeed the only, guide; for almost any result might be predicted from purely chemical arguments founded solely upon supposition.

The subject is important, and all data that can be collected must be of great service. As a matter of fact we possess photographs taken a score of years ago which, though we know them to have been printed upon foul-smelling paper, are equal to any in our collection in richness of tone and absence of signs of fading—saving only at their edges, where the air has had access to them.

The question is one peculiarly suited to our readers generally. We bring it before them, pressing it strongly upon their attention; and we invite them to contribute their experience with the two kinds of paper (pure and impure), to enable a fair judgment to be formed from facts rather than from fancy.

As will be seen from Professor Stebbing's communication, a fund is being raised in France for the purpose of erecting a monument to the memory of Poitevin, to whose discoveries photographers owe so much. We trust England will not be behindhand in subscribing to so deserving a fund. We shall be happy to receive and acknowledge any sums sent for the purpose.

Professor Dewar, in his lecture at the Royal Institution on *Flame and Oxidation*, exhibited a very curious experiment. The oxidising powers of permanganate of potash and of peroxide of hydrogen are well known to our readers; yet, notwithstanding this, Professor Dewar showed by experiment that the permanganate was oxidised by the peroxide.

The value of photographic evidence is very pointedly shown in the current number of the *Engineer*. Some very important artillery experiments have recently been made at Amager, near Copenhagen to test the projectile-resisting power of armour plates of various makes, and the journal we name gave a series of sketches of the plates after the impact of the shot. These pictures were objected to on the ground of inaccuracy, as also have other illustrations by another journal, and, in consequence, engravings of the official photographs have been given in their place. Both sets of sketches differ from the photographs—most conclusive evidence of the true mode of giving pictorial scientific evidence.

Anyone examining the *Illustrated London News* for the 1st instant will find in one of the pictures what forms a very ironical commentary upon our remarks as to the usefulness of photography for ensuring the truthful depicting of interesting scenes. We must make all allowance for artistic licence and the necessity for picturesqueness and soforth, but, really, even when that is all done, it is difficult to keep our risible muscles under control in examining what we presume to be meant as a serious picture—*The Convicts at Work at Portland.* To the immediate left in the foreground may be seen two convicts—certainly by no means of herculean proportions—toying with a square block of stone, which they appear to be jauntily moving out of the way of an approaching police officer, the said stone, from its size, weighing no doubt thirty or forty hundredweight. In the centre of the picture we have a somewhat similar block being hauled and pushed along the ground, by ropes, by half-a-dozen or so of these unwillingly-industrious workers. Can it be doubted that a photographic reproduction of such a scene would be of more interest than drolleries of this kind?

In Roscoe and Schorlemmer's great work on chemistry, which continues slowly to appear, there occurs a reference to cellulose, which may be alluded to by us as a reminder of one of the dangers of stored gun-cotton—applicable also, though in a less degree, to pyroxyline. Referring to the great explosion of gun-cotton at Stowmarket in 1871, which was shown to have been caused by the presence of acid in the stock of gun-cotton, these gentlemen say it was caused either by insufficient washing or to the felonious addition of acid. The coroner's jury sitting at the time found that the acid had been maliciously added; but, in any case, the warning to photographers to thoroughly wash their pyroxyline is equally strong.

There is an interesting reference to solar photography in one of the papers by Dr. Joule, which have recently been published in a collected form. He infers that the circumference of the sun's disc gives out a very feeble radiation compared with that from the central part, as measured by its photographic action upon a collodion plate.

We suppose a wholesale annexation of our articles is the penalty we have to pay for a widespread popularity and large circulation; but we do think that when our contents are appropriated a correct acknowledgment should be made. A few weeks ago we published the result of a long series of experiments we had been making upon the power of sulphite of soda as a developer. They are dismissed in about half-a-dozen lines by the editor of a little monthly series of jottings as being the process of a gentleman whose experience with our suggestions was published in a letter to these columns. Annexers, kindly take note!

A statement which, if founded upon actual fact, contains information that might be of great usefulness to photographers was published a little while ago in an American technical journal. The writer avers that if a very thin coating of glycerine be applied to a glass surface it will entirely prevent any moisture settling—meaning, of course, the condensation of aqueous vapour in the form of small globules, similar to the well-known effect produced by breathing upon a plate of glass. As an example of the potency of the plan, he goes on to say that "if used on a looking-glass you can shave yourself in an ice-house and the glass will not show your breath. * * * In fact, it can be used anywhere to prevent moisture forming on anything. It does not injure the usefulness of field glasses, &c. * * * I first saw this used on a steam-gauge glass on a Sound steamer where the gauge leaked inside." It is not a difficult matter to put to the test, and it is obvious that the plan would possess a wide sphere of usefulness. In such experiments, for example, as photographing the laryngeal chords, described by us a few months ago, it would materially facilitate the employment of the necessary mirrors. Indeed, the many uses that could be made of such a convenience will at once present themselves to our readers. That even in very thin films it should have no effect upon a lens must, however, be received with some little doubt.

Mr. E. C. C. Stamford read a paper before the Society of Arts which was full of details most interesting to photographers. The communication was *Upon the Economic Applications of Seaweed;* and the writer dwelt very fully upon the extraction of iodine and bromine, which, as many of our readers are aware, used at one time to be extracted wholly from "kelp," the name given to burnt seaweed—formerly the chief source of the carbonate of soda used in this country. Chloride of potassium was obtained from one variety—that richest in iodine—and was worth twenty-five pounds per ton. Immense alkaline deposits were discovered on the continent, and the chloride became so plentiful that it dropped quickly to a third of this price. Bromine was then discovered (also in the deposit), and in such quantity that, instead of being able to fetch thirty-eight shillings per pound in the market, it gradually dropped to fifteen pence—its present market price. Iodine is extracted largely now from the caliche of Peru, so that "kelp" is no longer used, either for bromine or iodine extraction, though Mr. Stamford has introduced such improvements that it may be worth while if his suggestions should be carried out to recommence such extraction. Iodine itself has kept a fair average price, twelve shillings being now obtainable, the highest decimal average having being fifteen shillings and elevenpence.

Of course everyone knows that the sea contains vast quantities of dissolved silver, though no one has yet been able to extract it in paying quantities. Similarly, it contains iodine and bromine. The quantities found by Mr. Stamford were of iodine not more than one part in two hundred and eighty millions, but of bromine there existed one part in sixteen thousand. It might be thought, from analogy with the continental potassium deposits, that our English salt mines might contain bromine, but such is not the case. The Cheshire mines have been subjected to a careful examination without any success. At the present low price of bromine, however—which (except through occasional speculative purchases) is not likely to be increased—there need not be much disappointment. Bromides are quite as cheap as is necessary for photographic purposes.

HOW TO MAKE AN IODIDE EMULSION.

An inquiry in our correspondence column points out a difficulty which has been experienced by a large number of emulsion experimentalists, namely, the granular formation of the iodide of silver. The granulary of silver iodide differs so much from that induced by boiling, or other means in the case of bromide, that, instead of remaining in the emulsion to impart coarseness to the resulting film, it is either precipitated or removed in the course of filtration. It thus happens that, by some methods of emulsification, it is quite possible that no iodide whatever may be present in the finished film, though a liberal proportion may have been employed in the formula.

Owing, therefore, to the readiness with which the iodide assumes the granular form, it is important in emulsifying or mixing to use every endeavour to counteract this tendency. But as the means adopted for that purpose are, as a rule, identical with those which conduce to the production of a slow emulsion, or which require a considerable prolongation of the period of cooking, it is plain that in making a mixed emulsion we are scarcely at liberty to do as we please in connection with the iodide.

Under such circumstances—*i.e.*, when a bromo-iodised emulsion is to be made—perhaps the best plan is to add the silver, slightly acidified, to the concentrated gelatine first of all; to that the soluble iodide is next added (and this may, with advantage, be mixed with a separate portion of the gelatine), and, finally, the bromide is stirred in. By this method the iodide of silver is formed in the presence of a large excess of silver nitrate and also in a concentrated solution of gelatine; the solvent action of the nitrate of silver materially aids in imparting fineness, as does also the thick gelatine, and if the bromide be subsequently added gradually the iodide retains its fineness to the end of the operation.

Another plan, where the proportion of iodide is not large, is to precipitate it separately from aqueous solutions, and, after washing, to dissolve it in the concentrated silver solution, to be added to the bromised gelatine. Here, as the silver nitrate is gradually decomposed, the solvent power of the solution gradually decreases, and the iodide is precipitated in a fine state of division.

The method of forming a fine bromide, and, subsequently, by the addition of a soluble iodide, converting a portion into silver iodide, does not—at least, in solutions poor in gelatine—have the desired effect, as the particles of iodide are as likely to be coarse as not.

Where a plain iodide emulsion is in question the matter is to a great extent simplified. There is no necessity to "cook" the iodide for the sake of sensitiveness, as it is doubtful whether any such treatment is productive of effect except physically. We can, therefore, mix in the presence of the full quantity of gelatine, and, indeed, the solution of that may be concentrated, if desired, so as to render the mixture as viscid as possible, and so prevent the formation of coarse iodide. It is surprising, however, even under these conditions, how large a quantity of granular matter will be found left upon the filter.

In order to produce the most perfect fineness it is possible to obtain we have frequently proceeded as follows:—Weigh out the necessary quantity of silver nitrate, say 100 grains, to make five ounces of emulsion, and dissolve it in (say) two ounces of water, to which add fifty grains of gelatine and two minims of nitric acid. In another two ounces of water dissolve fifty grains of gelatine and forty grains of *chloride* of sodium. When dissolved mix the two solutions, stir carefully and keep in a warm place for an hour, then allow to set. We have now an emulsion of chloride of silver which, as is well known, forms in an extremely-fine state of division—so fine, indeed, as to form perfectly transparent films even when a large proportion of the chloride is present. An interesting illustration of this consists in taking an ordinary transparent gelatino-chloride film and dropping upon it a drop of a ten-grain solution of bromide or, better, iodide of potassium; the result will be the conversion of the transparent chloride of silver into more or less opaque bromide or iodide, while as the particles are held in the solid film they can scarcely undergo much coarsening.

This is precisely the line upon which we next proceed with our chloride emulsion. Having permitted it to set in a beaker or other convenient vessel we pour upon it a solution composed of iodide of potassium, one hundred and twenty grains dissolved in two ounces of water. The conversion of the chloride into iodide will proceed slowly from the upper portion of the mass, until at the end of a few hours it will have penetrated completely through it All that now remains is to break up the emulsion and wash it in the ordinary manner.

A quicker and perhaps more satisfactory method is to break up the chloride emulsion into the solution of iodide, when the conversion proceeds with great rapidity, and the washing completes the operation.

The result is in either case an emulsion of the most exquisite fineness, but it will be found that if kept liquid for any length of time the iodide subsides and conglomerates into coarse particles. It is, therefore, desirable to preserve the emulsion under alcohol or in the dry state until required for mixing with a larger bulk of gelatino-bromide, when in its more dilute form the iodide shows less tendency to agglomerate or become coarse.

As the efficacy of the iodide depends solely upon the fineness of its division the value of this method will be recognised. It may seem a somewhat roundabout way of arriving at the result, but when the ease with which an exquisitely-fine chloride emulsion can be made is taken into consideration, as well as the simplicity and certainty of the subsequent operations, it will be found to be a real gain.

ON A MODIFIED FORM OF TRIPOD.

The photographic tripod stands, as now commonly employed, answer well for general purposes; but there are many special cases where none quite fulfil the conditions required. Those with fixed heads are all right for working upon firm and moderately-even ground; but to level the camera upon one on beach or loose and uneven soil is no easy matter, and takes up much time. The adjustable head is an improvement upon these; but still there is waste of valuable time in levelling the camera, for very few photographers avail themselves of the circular level to assist their judgment and ensure accuracy in this particular. How great a proportion of architectural photographs are spoiled by distortion from this cause alone, the lens often being blamed for defects of this character entirely attributable to slight tilting! The ball and socket, as hitherto constructed, labours under the same disadvantage. Not any of the above are suitable for photographing from boats or any swaying platform, because the rigidity of the tripod head makes the camera a fixture to the boat, and causes its point of sight to be changed skywards or waterwards as the boat pitches and rolls.

The modification of the tripod or addition to the ball and socket (whichever you like) I wish to bring to notice will be without these defects, the portion of head bearing the camera either swinging free of the other portions or being made rigid at will. It consists in drilling an inch hole through the triangular piece (about two inches thick) to which the legs are fastened, and, further, in turning out the top of the hole into a semispherical hollow about two inches in diameter, and in slightly coning out the hole on the other side of the piece. This is the seat for the ball. A cap of metal, with a cavity of like dimensions and drilled with an aperture of an inch and a-half or more, to be strongly but loosely hinged to one side of the first-named hollow and a set screw on the other, secures and binds the ball. This completes the socket, which is in all respects similar to others, excepting that it has a larger opening underneath.

The ball of wood or metal to fit the socket is turned upon a rod which projects to the extent of fifteen or eighteen inches, with a thickness of from five-eighths to three-quarters of an inch on one side of the ball and about three inches on the other, but conical from the ball outwards to give strength and substance for framing it securely to the board which is to bear the camera. The ball is then placed in the socket by passing the long end through the hole, the cap is placed over, hinged, and the binding screw fixed. The lower end of the rod being furnished with a hook, an india-rubber door spring, with string and loop, completes the tripod.

Its use is as follows:—When set up the foot is placed in the loop and the binding-screw released, and the camera is immediately drawn level and clamped. If used on shipboard a weight is hung upon the hook and the binding-screw unfastened. The head is then free to accommodate itself to the motion of the ship by retaining its level in all circumstances of pitching, tossing, and rolling, to which the platform supporting the tripod is subject.

For ordinary use the camera case would be sufficient to keep it steady, and one might always rely on the instrument being level. The head may be made in metal or wood—if the former, cast hollow, and all superfluous portions removed to keep down weight.

John Harmer.

OBSERVATIONS UPON FADING.

[A communication to the Photographic Society of Great Britain.]

So much has been said and written upon this subject that it might be thought almost superfluous to attempt to throw new light upon such a worn-out topic; but the supreme importance of the matter, coupled with the fact that discussion has been re-opened by the reading of a paper on *Old Photographs*, by Mr. E. Dunmore, at the March meeting of the South London Photographic Society, must be my justification for once more returning to the subject.

The conditions of permanence are tolerably well understood by photographers, and, so far as regards silver prints, much more care is taken at every stage of their production than was formerly the case. By the liberal use of fresh hyposulphite, and subsequent removal of the excess of fixing salt by very thorough washing in water; the employment of alkaline, or, at least, well neutralised gold toning baths; silver sensitising bath, not too weak; negatives not too thin—all are points to which attention must be paid, and, so far as my inquiries lead, are now generally observed.

The photographer, having done his best, is now unhappily at the mercy of the paper-maker, for he must needs mount his pictures in some sort of presentable form, and these perchance will find their way into portfolios or albums. What, now, if after all the operator's care and trouble in the exclusion of every trace of hyposulphite from his finished print, he proceeds to mount it upon a cardboard impregnated with this very substance? Or if, careful himself about the card mount, his client thrusts it through the grooves of a mass of paper stuff in the shape of a common album, or puts it behind a heavy "cut mount" of doubtful constitution, with a view to its better preservation!

Sixteen years ago I pointed attention to the *Occurrence of Hyposulphites in Mounting Cards*, in an article written for the *Photographic News*, which this Society did me the honour to reproduce in the *Photographic Journal* for May, 1868 (vol. xiii., p. 54). It was there shown that cardboard was seldom or never free from hyposulphite, and a mild appeal was made to paper manufacturers to abstain from using this salt as "antichlor." Now that the subject of fading is again to the front it seemed to me desirable to re-open this old question, and I have been testing cards and mounts and making a heap of inquiries of the paper-makers. My report, briefly stated, is as follows:—Hyposulphite still to be found in cards of recent make, and the practice of using this salt as antichlor generally admitted by the English paper-makers.

Without mentioning names I may say that the testimony is most conclusive as to its continued use; but I am not without hope that experiments now being tried on the large scale, on improved methods of manufacturing paper-pulp from wood, &c., by the bisulphite of magnesia process, will result in the introduction of a new system likely to be of considerable benefit to our craft. If this should succeed—and I hear favourable reports from several quarters—a revolution of manufacture will be brought about, and henceforth no antichlor will be necessary. At the recent *soirée* of the Chemical Society (April 24th) Messrs. Cross and Bevan exhibited some samples of Ekmann's new paper-stuff, made by the disintegration of wood under great pressure and boiling with the bisulphite solution, and these specimens certainly looked like the right article. On the same occasion Messrs. A. Boake and Co., of Stratford, exhibited a large series of sulphites and bisulphites, as used by paper manufacturers. I am told that Ekmann's pulp can be mixed with an equal quantity of white rag pulp to make the finest paper, and that there is no necessity to employ hyposulphite. If this experience be confirmed we are out of our difficulties. On the other hand, we know there has been of late a demand for extra-thick mounting boards, which could only be supplied at a low or moderate cost by the use of very inferior materials, faced and backed with a better quality of paper. This, of course, offers no guarantee of permanence to the photographer, and the black or highly-coloured tablets are often the worst of all.

Tracing the history of this "antichlor" proceeding I find, on reference to the English patents, that in the year 1852 (November 26th), Thomas Ainsley Cook filed a petition for "Improvements in Bleaching," described as follows: — "In all bleaching operations where chlorine is employed it becomes necessary to take up or neutralise any chlorine that may be in excess. Now, my invention consists in the use of any of the following salts:—Hyposulphite of lime, of soda, of ammonia, of potash, of magnesia, or of alumina, which I apply to the goods after being treated with chlorine, when the hyposulphite used will neutralise any excess of chlorine that may remain in the material bleached."

Eighteen months later (May 9th, 1854) Eben Norton Horsford took out a patent, No. 1,038, for the "Removal of Chlorine from Substances and Fabrics." This invention "consists in neutralising chlorine by means of the substance called 'antichloride of lime,' which may be prepared by passing the fumes of burning sulphur into milk of lime, contained in a suitable vessel provided with agitators. The antichloride of lime, being collected on filters, may be dried and preserved for use. It may be applied by adding a small quantity directly to the pulp engine; or fabrics out of the 'chemic' may be passed through water slightly acidulated, containing in suspension a little of the antichloride."

Here, then, it will be seen that sulphurous acid was proposed to be used instead of the hyposulphite. On tracing back, however, to the earliest mention of the use of sulphites in paper-making I find a prior claim in favour of John Donkin (October 15th, 1846, No. 11,417); and, as I shall presently show, it is a true misfortune for us that at this early date the manufacture of bisulphite of soda was not sufficiently perfected to allow of its general use as an antichlor, or we should have been spared many of our troubles during the last thirty years. The specification runs thus:—"Improvements in the Manufacture of Paper, or in the Machinery Employed Therein, and in the Process of Bleaching Paper, Linen, and Other Manufactures in which Chloride of Lime is Employed." By disclaimer (dated March 22nd, 1847) the title of this patent is altered to "Improvements in the Manufacture of Paper, and in the Process of Bleaching Linen and Other Manufactures in which Chloride of Lime is Employed." This invention consists in "the application of bisulphite of soda in solution to paper, pulp, linen, and other articles or materials which have been bleached by means of chloride of lime, so as to decompose and get rid of the chloride of lime which may be remaining mixed therewith or attached thereto." In practice the patentee has found that "about a pound of the saturated solution of bisulphite of soda is sufficient for decomposing the chloride of lime in the pulp obtained from a hundredweight of rags, when the pulp has been well drained or pressed."

By all means let the paper-stuff be well washed from the bleaching lime and other salts subsequently applied as antichlor; but, in order to determine by actual experiment the relative effects of sodium sulphite and hyposulphite if left inadvertently by the paper-maker, I took two photographs (silver prints), cut them in halves, and submitted them for equal periods of time to the action of these two solutions. The results (exhibited) show that sulphite of soda has no appreciable effect in forty-eight hours, whilst the other portions of the prints immersed in the hyposulphite are considerably bleached, or, as we should say, badly faded.

These striking differences are borne out again by another experiment which I then made. Clean a few sixpences or small silver coins, put them into sulphite of soda solution, weak or strong, hot or cold, and leave them there for an hour. Pour off the top liquid, and test for silver by adding a drop of sulphide of ammonium. No trace will be found dissolved. Now try a similar experiment with the hyposulphite using the same coins, and we shall soon find very distinct evidence of silver in the solution, showing that the metal has been attacked and dissolved by the combined action of air and hyposulphite, forming the well-known double salt of sweet taste.

With these facts before us, the fading of a silver photograph becomes perfectly intelligible, and the necessity for thorough washing and careful exclusion of hyposulphite from the finished print becomes at once apparent. I have described these results somewhat at length, because they furnish an answer to Mr. Dunmore's extraordinary statement that "fresh hyposulphite, even as strong as a twenty-per-cent. solution, applied to and left in the prints and dried in the usual way, has no effect whatever on their permanence."*

Forced to indicate the cause of fading, the last-named author attributes the deleterious effects, wherever it arises from the mounts, to the presence of chlorine (excess of bleach) rather than to the hyposulphite. I have looked into this question also, and certainly find soluble chlorides in the cheaper sorts of cardboard, with plenty of sulphates and all kinds of mineral rubbish, but never met with *free chlorine* in the finished mounts. It would most likely be absorbed by the sizing, if traces only were left in the pulp.

Now, in the event of the paper-makers accepting the suggestion to use sulphite instead of hyposulphite, how would this affect the iodide of starch test, upon which we have been accustomed to rely for the detection of the last-named ingredient? It is known that sulphite of soda will also quickly discharge the blue colour of the starch compound. Thus far no difference. But we have a ready method of distinguishing between them, for the sulphite instantly discharges the colour of weak magenta, whilst the hyposulphite has no such action. This, then, ought to be the paper-maker's guide as to the quantity he should add to the bleached pulp — so much as will neutralise the chlorine and yet not discharge the colour of highly-diluted magenta. Messrs. Giles and Shearer have gone fully into the testing of sulphites in a recent communication to the Society of Chemical Industry, which was printed in their last month's *Journal*. They worked upon some very pure samples of crystallised sulphite of soda made by Messrs. A. Boake and Co., on a large manufacturing scale, which tested over ninety-nine per cent. This proves that high qualities are now procurable, which was not the case when Donkin took out his patent.

Mr. Valentine Blanchard, in speaking of "The Finished Photograph,"† says:—"In a conversation with Mr. England some little time ago on this subject (fading) we confirmed each other's experience that prints mounted on a lithographic tint were more permanent than prints on the ordinary board. The reason for this is not difficult to find. The thin layer of greasy ink keeps the photograph from contact with any deleterious matter in the board, and that such matter exists in a great many samples of pasteboards is only too well known to most of us."

The selection of tinted mounts in preference to pure white is always to be recommended, for then the paper-stuff need not be so highly bleached, and a further precaution is the final application to the photograph of an encaustic paste, which, by diminishing the hygroscopic qualities, helps to shut out the influence of moisture, always so detrimental to the permanence of a photograph exposed in our variable climate.

I have only to add that Dr. Hugo Müller informs me that in South Germany the makers have entirely given up the use of hyposulphite, and he says the same of North Britain. From another source I learn that the paper-makers of Angoulême tried to do without it a few years ago, but have gone back to the old practice. Perhaps now the reduced cost will again offer encouragement to the use of sulphites; if so, the photographic community will be well content to hear that a fertile cause of fading has been banished for ever. JOHN SPILLER, F.C.S.

FOREIGN NOTES AND NEWS.

PROFESSOR H. W. VOGEL IN MOLL'S *NOTIZEN* ON THE INTENSIFICATION OF GELATINE PLATES.

IN Moll's *Notizen* Professor H. W. Vogel, writing regarding the intensification of gelatine plates, says that when gelatine plates first came into use many people thought that any intensifier that was suitable for collodion plates would do for gelatine plates; but they soon discovered their mistake, and at length found themselves almost limited to mercury. Mercury worked admirably, but, alas! for a plate intensified with it when one wanted to use it after it had been lying by for some time! Dry-plate makers now endeavour to make their plates so that they shall not require to be intensified; but for all that it occasionally happens in dark weather that the portraitist has to intensify, and it frequently occurs that the landscape photographer finds his negatives print too flat, and therefore urgently requires a reliable intensifier. For a long time it was not understood why so many kinds of development did not succeed with gelatine plates, but it is now known that the gelatine itself is affected by many of the chemicals used, while collodion is a perfectly indifferent substance:—

"Dr. Eder has just recognised that not only red prussiate of potash, but also uranium salts, have a tanning action upon gelatine they harden the film and at the same time obstruct the passage into the interior. It is therefore, explicable that the uranium intensifier, which has such an excellent effect upon collodion plates, containing as it does a mixture of both the tanning materials, should have but a bad effect upon gelatine plates. For the same reason it is difficult to do anything satisfactory with lead intensification with which red prussiate of potash is used. Chloride of iron, which can be used on collodion plates like chloride of mercury, has also a tanning action upon gelatine, and therefore acts as its own prohibition. Permanganic acid is reduced by the gelatine film, and the latter also becomes coloured by it at places where it should have remained transparent. Lastly: iodine applied in solution to the gelatine film is retained so obstinately by the latter that the brown colour produced by it can only be removed after long-continued washing, and consequently it seems impossible to seize the right instant for breaking off the intensification. It is also difficult to do anything with the ordinary silver intensifier. The reason here lies less in the slightly-tanning action of the pyrogallic acid than in the difficulty with which it penetrates the gelatine film. In five minutes a collodion plate is washed and finished; a gelatine plate requires at least half-an-hour—a proof of how difficult it is for the chemicals to go out of the latter. They have equal difficulty in penetrating it, and that is so much the worse in that the chemically-developed gelatine picture lies much more within the film than the physically-developed collodion picture. The fact is that in the case of physical development the silver is precipitated much more on the surface, and consequently remains much more accessible to chemicals, and therefore to intensification. This circumstance alone greatly facilitates the intensification of collodion plates.

"From the foregoing it is clear that for the intensification of gelatine plates those chemicals are most suitable, firstly, which exert no influence upon the gelatine itself, and, secondly, those that penetrate the film and are most easily removed again. So far as our present knowledge extends, the mercuric salts of silver fulfil these conditions best. Now, these are recommended in the most various modifications. I may here mention the chloride of mercury and ammonia intensifier; Edwards's intensifier, chloride of mercury with iodide of potassium and hyposulphite of soda; and Eder's intensifier, chloride of mercury with iodide and cyanide of potassium. The last-mentioned intensifier works very well, only the cyanide of potassium solution soon decomposes. More cyanide of potassium must then be added to freshen it up. The carbonate of soda formed by its decomposition has a dissolving-off (loosening of the film) action upon many gelatine films. Edwards's developer keeps better; but, as Eder has shown, it soon eventually decomposes with formation of mercuric sulphide. With regard to the ease with which these three intensifiers can be washed out of gelatine films we have no experiments before us; but I know some experienced, practical men who complain that in time negatives treated with Edwards's developer become yellow, while those intensified with mercury chloride and ammonia do not. That speaks in favour of the latter intensifier, and I can only agree with it. It is, however, the fact that negatives intensified by it have not proved durable; here the imperfect washing bears the blame. It is urgently necessary that plates should be thoroughly washed immediately before being treated with mercuric salts in order to remove every trace of hyposulphite of soda, and then (though this is often neglected) again *after* the treatment with chloride of mercury, with dilute ammonia, which turns the plate brown, for at least half-an-hour, in order to remove every trace of the mercuric salt; after that a short washing suffices. If one proceed in this manner he will not have to complain of spoilt negatives."

EXPERIENCES ON THE THAMES.*

WE made up our minds to keep to a certain number of good resolutions before starting. One was that we would always be out at 5 a.m., our photographic friends strongly advising that course. This was, like the rest, "more honoured in the breach than in the observance;" for it was 8 a.m. before we found ourselves in the hotel coffee-room, and nearly 9 a.m. before we had made a move towards the river. It was still windy and rough, and, worst of all, a head wind. Between 10 and 11 a.m. we took an affectionate farewell of Salter's *employés* and made our final start, one of us taking the sculls as before.

We had proceeded in this comfortable fashion for half-an-hour or so, getting farewell "shots" at the university barges and Oxford, when "one of us"—not the coxswain—suggested the advisability of a change of programme as regarded progression, and that it might be as well, now we were out of sight of Salter's people, to try towing. This we did; but the coxswain, at our next halt, thought it highly undignified to begin towing so soon, and suggested that we should take an oar apiece. To this we both agreed. Unfortunately, under these new conditions our lugger would not go straight, but always had a tendency towards one bank. This caused some chaffing, and "one of us" (the culprit) put forth a gigantic effort to alter this state of things. It was at the same time a bold and irresistible effort, and the result was that before we knew where we were or could slacken speed we had charged full tilt into the trunk of a large old willow at the bank. It nearly upset us and "shivered our timbers" from stem to stern. A further result was to cause the Philosopher, who was too deeply absorbed with his philosophic calculations to notice such a trivial occurrence, to place his feet where his head should have been, and *vice versâ*, and on sufficient recovery of self-possession to exclaim—"What is it?" Luckily no one saw our *contretemps*, so that we made our investigation in private. We found the tree had suffered more than ourselves. Our lugger had happily not sprung a leak; our baggage only was scattered in all direc-

* *Photographic News*, March 14th, p. 140.

† *Year-Book of Photography*, 1884, p. 77.

* Continued from page 363.

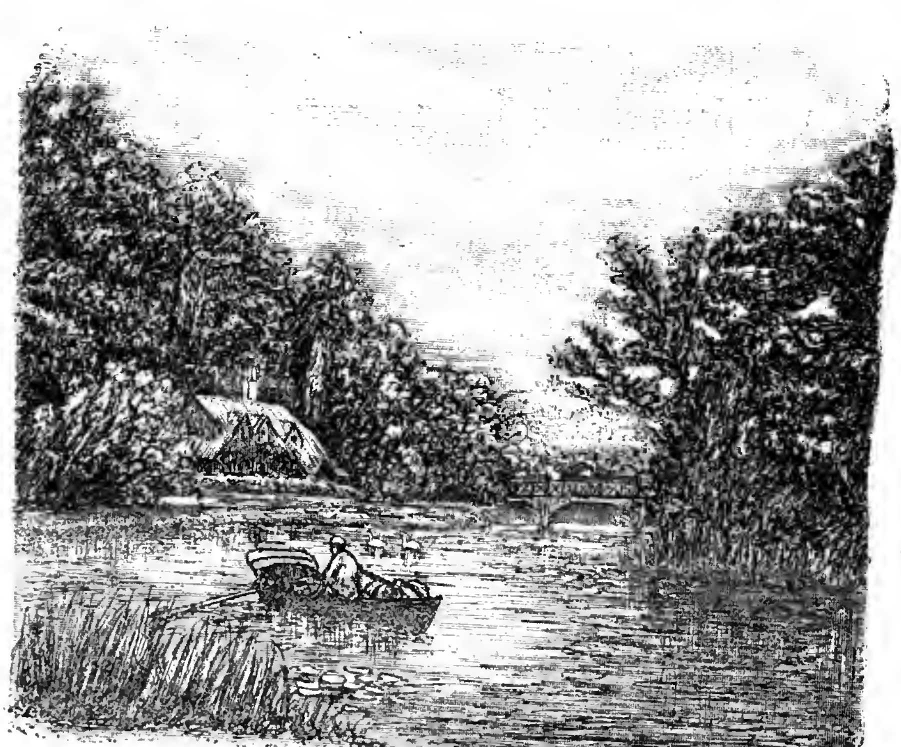
tions, and our nerves somewhat shaken. The tree had fared badly, for we had rammed a big hole and carried away at least a square foot of bark as a trophy. We held a council, and decided to try ramming no more.

Another short pull brought us to Iffley, where we passed through our first lock—a fall of some four or five feet. At Iffley we had a "shot" at the church—a very ancient Anglo-Norman structure supposed to have existed prior to the twelfth century. This is by no means one of the prettiest along the river, and we failed to get a good near view. Iffley Lock absorbed another plate or two, and then we came just below the lock to Iffley Mill—a very ancient and really picturesque "bit;" and, as it was the first we had come to, it was duly appreciated and we tried to do justice to it. The third illustration is one of the views we obtained.

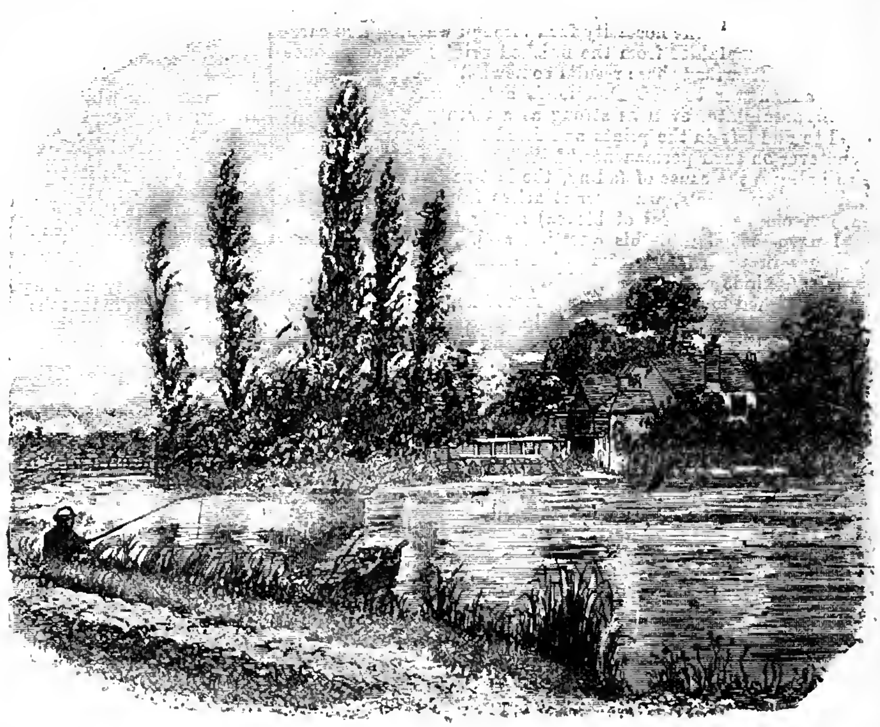
Rarely did we find such a variety of interest for the camera as between Oxford and Iffley. We now each took an oar and were proceeding fairly satisfactorily and cautiously, when suddenly the Philosopher stopped rowing. In alarm I asked him what was the matter. His face had visibly elongated, and in measured tones he replied—"Why! do you know the force required to propel our man o' war (this was the last name it had acquired) increases as the square of the resistance; so that, for instance, the force required to drive her three miles an hour—supposing that feat possible—is just nine times that required to drive her one mile an hour?" I confessed the question had not occurred to me, and that it was very serious. The only remedy was to go back to Oxford and change our "three-decker." This we decided not to do.

Resuming our voyage in a rather disconsolate mood, our next point of attraction was Sanford Lock—an example of one of the many picturesque combinations of lock, weir, and mill. Here we exposed a couple or so of plates and obtained satisfactory results, to which our decoy ducks added some effect.

From Sandford the river increases in picturesqueness until we reach a climax of beauty at Nuneham Courtney. This, the seat of the Har-



court family, is the subject of our illustration, and is certainly one of the finest and prettiest spots on the Thames. The park is well timbered and covers something like 1,200 acres. The magnificent trees hang luxuriantly over the river, and form a perfect wealth of foliage piled on the rising banks. The whole property was purchased for only £17,000 by the first Earl of Harcourt. Those pretty rustic cottages we see in the illustration have been erected for the convenience of picnic parties; for Nuneham Courtney has long been a favourite holiday resort for Oxford students and citizens, and all the summer through



pleasure-seekers leave Oxford for a day amid the shade of those umbrageous woods, or within those cottages erected solely for public accommodation by the Earl.

Our first "shots" were in the evening, just after sundown. Thinking there was little light we gave twenty seconds' exposure, but on developing at our hotel later on in the evening we found we had hopelessly over-exposed, the probability being that two seconds, or less, would have been sufficient. A further pull brought us to Abingdon, where we stayed the night and became acquainted with our error of judgment, thus showing the value of being able to develope *en route*.

Next morning, instead of progressing, we made a retrograde movement in the direction of Nuneham. This time we obtained good results, in which our boat and accessories (the ducks, &c.) were turned to useful account. On our return from Nuneham, the Philosopher suggested he should take both sculls. As I had certainly no objection to doing a little *dolce far niente* at the stern of the vessel I willingly accepted the offer. The Philosopher intended to do a little "show off" this time, but before he had made twenty strokes there was a sudden elevation of his feet with an opposite depression of his head in the direction of the bottom of the river. Curiously enough he had previously remarked—"How nice it would be to have a dive in the cool, limpid water!" When the Philosopher became sufficiently acquainted with the state of things at the bottom of the boat he quietly suggested—"This is very much like catching a crab." I remarked it was the finest species of the crab genus I had ever seen. Again we were thankful; there had been no "spill."

The first pretty view of Abingdon we obtained on our return was a general one which embraced the church steeple, bridge, and sweep of the river. Further interesting views of Abingdon we also secured at the other side of the bridge. Abingdon is a pretty old town and used to be a place of considerable importance, and many stirring events of English history have been enacted there. Today it is quiet, dull, and clean, like many another town whose small manufacturing industry has long since departed, leaving it solely dependent on agricultural interests. It is narrated by easy-going chroniclers that the Mercian Kings used to reside at Abingdon; and as early as 686 a monastery to the Virgin Mary was founded for the monks of the Benedictine order—those good monks who so nobly devote themselves to the manufacture of a cordial of that name, and, in the words of the Philosopher, I add, "long may they live to make it!" The abbey was unfortunately later on burnt by the Danes, and the ruin of the monks was completed by King Alfred, who took away the estates from these militant saints for not having resisted the enemy with sufficient zeal.

A new abbey was built, which suffered various vicissitudes until its final demolition early in the sixteenth century. The remains of the thick walls can still be seen. During the civil war Abingdon played an important part in the contest, being first established by Charles I. as head-quarters for his horse, but subsequently taken by the parliamentary forces. There are many interesting churches at Abingdon. That of St. Nicholas, the Roman Catholic, in the Market-place, is an old Norman edifice. St. Helen's church stands close by the river. Its spire is a conspicuous object up and down the river for some distance, and in every general view of Abingdon, from any point, it always forms a very prominent feature.

J. J. Acworth, F.I.C., F.C.S.

(To be continued in our next.)

ILLUMINATION OF THE DARK ROOM.

[A communication to the Photographic Society of Great Britain.]

The preservation of one of our most cherished faculties—that of sight—is of so much importance to our comfort and well-being that it is proper to give full consideration to the question of how it may be affected by the light in which we work.

Mr. W. Ackland remarks that, since the introduction of red light into photographic dark rooms, he has observed a remarkable increase among photographers, more than others, of failing sight. On this ground he deprecates the use of red light, and recommends the employment of one of a cooler character.

Dr. G. A. Herschell writes:—"Unfortunately for the dark-room operator, red light of all colours is a great deal the most injurious." By those who advocate the use of red light in the dark room other reasons have been sought to account for the photographer's special liability to failing sight. To some extent these reasons may co-exist with the evil influence of the red light. There have even not been wanting those who say that they prefer a red to a yellow or greenish light as a matter of personal comfort; but I am sure that the great majority feel the fatigue and irritation to the sight of working in red light, and would gladly change it for light of a cooler colour if they were aware that the necessity for using a red light, which has been so long insisted upon, is a mistake, and that yellow light of the same degree of illuminating power has no more effect upon the photographic plate, if as much, as the long-vaunted ruby.

The question naturally arises—How is it that if there were no necessity for red light, it came with the introduction of gelatino-bromide plates to be insisted upon and almost universally adopted? It was because it was said that bromide of silver was—compared with the wet-plate collodion, the sensitive compound of which consisted mainly of iodide—much more sensitive to the yellow light in particular, and that red light must therefore be used for bromide, whereas yellow was proper for iodide, manipulations.

It has often been stated that bromide of silver, whether in the form of collodion or of gelatine emulsion, is more sensitive to the colours of the middle and lower part of the spectrum, and will represent these as lighter, compared with the blue and violet, than the old collodion bath plate, which ordinarily consisted of iodide of silver and a small proportion of bromide. So strong a hold had this idea upon the minds of photographers that when collodio-bromide emulsion came into use, although it was less sensitive as a whole than bath plates, it was said it was so sensitive to yellow and orange light in particular that it was necessary to use red light for the purpose of the dark room, and plates were stated to be fogged in a laboratory the light of which did not injure the bromo-iodide bath plate. This probably arose from the much longer time that bromide emulsion plates were exposed to whatever light was used during their preparation and lengthened development than was necessary with bath plates.

When rapid gelatine plates first came into common studio use it was during a winter season, and it was asserted that their rapidity was due to their greater sensitiveness to the yellow light of winter; and it was predicted that when the spring and summer came round it would be found that they would be no more sensitive than the accustomed collodion. This was found to be a mistake, and the most careful experimenters could find no difference in the relative sensitiveness of the two processes in the winter and summer seasons.

Captain Abney, when recommending the use of a small portion of iodide of silver in bromide emulsion, stated that this addition so changed the range of sensitiveness of the compound, by lowering the sensitiveness to orange light, that plates containing a small quantity of iodide might be safely developed in such light, whilst those containing pure bromide only and of equal general sensitiveness were so sensitive to orange that a red light only must be employed in the dark room. Dr. Eder stated recently (*Photographische Correspondenz*, April, 1884, page 95) that the addition of iodide renders the plates more sensitive to the yellow and green. Considering that yellow and orange are so close together in the spectrum, and that the bulk of photographic action is at the other end in the blue and violet and beyond it, these statements are almost exactly opposed to each other.

I have here a sheet of coloured ribbons, made up of violet, blue, green, yellow, orange, scarlet, and crimson. The colours, of course, are not as pure as those of the spectrum, but they are much purer and brighter and should produce more difference of photographic effect than the colours of natural objects with which the photographer ordinarily has to deal, and in the delineation of which spectrum photography professes to direct him.

For photographing these I have prepared three emulsions—No. 1 containing bromide only, No. 2 containing five per cent. of iodide, and No. 3 ten per cent. The emulsions were prepared in other respects in a similar manner, and were made by the boiling process. Here are photographs produced with these emulsions, and I think you will not be able to find any difference between the results sufficient to be positively affirmed. In each case the violet has come out the strongest, and then the blue. From the green downwards the colours have all come out in each plate of nearly equal depth, but it will be noticed that the yellow and orange have had less effect upon the plates than the reds. Probably some white may accompany the reds, although they were the purest colours I could obtain in ribbons; still the main point is that with each plate the result is about the same. From this we gather two things—first, that the addition of iodide does not make that difference in the range of sensibility to the colours presented to the camera that has been stated; and, secondly, that if we were to work in our dark rooms by light reflected from these surfaces we should choose the yellow and the orange, as having less effect upon the plate than the reds, and giving at the same time far more luminosity.

About a year ago Mr. J. R. Sawyer showed a somewhat similar sheet of coloured ribbons and photographs from them, in which it was remarked that each colour came out lighter or darker than another in precisely the same series, whether the negative had been taken on an ordinary bath plate consisting of iodide and a small quantity of bromide, or of a gelatine plate containing bromide and a small quantity of iodide. There was not, however, among Mr. Sawyer's experiments one with a plate containing bromide only; and it is to compare this with plates also containing iodide, and to examine the alleged effects of this addition, that these experiments are made.

At one of the technical meetings of this Society I brought forward a lantern, the four sides of which were glazed with different materials, the two most contrasted of which were two thicknesses of ruby glass in the one case, and in the other a yellow produced by two thicknesses of yellow paper and one of a yellowish-green glass. The latter combination was considered by all those present to give a much better, as well as a more agreeable, light to work by than the rubies, and at the same time it had been found to produce at a given distance much less effect upon a sensitive plate.

Captain Abney, at the March ordinary meeting of the Society, followed with a paper in which he spoke of the question, which he had considered settled, as having been re-opened, and, without referring specifically to the particular light that I had compared, maintained that red was better than yellow for the purpose of dark-room illumination, selecting as the types for comparisons a glass known as "stained red" and a yellow paper known as "canary medium." Now, the stained red glass has this peculiarity—that it appears a red, but is really formed by the piling up of yellow. It is a curious fact that if a clear, transparent yellow be taken, and fresh thicknesses of the same added, the transmitted colour becomes orange, and finally to the eye red, although when examined with the spectroscope it will be seen that the yellow still passes; and this adds to the luminous effect to the eye, although the existence of the colour is unperceived. Every one who has used bichromate of potash solution must have noticed that a thin layer appears pure yellow, but a thick one orange, and if very thick red. Stained red is a silver-stained glass in which the quantity of silver is sufficient to give an orange-red appearance instead of the yellow which a thinner layer shows. I have here a wedge made up of increasing thicknesses of stained yellow, where it is seen the colour passes from a pale yellow to a reddish-orange. More thicknesses would show a colour identical with that of the stained red, except for the fact that the natural greenish tint of so much ordinary glass would have its effect. If a piece of stained red be broken it will sometimes happen that it will chip a little so as to divide the layer of stain, when, as in this piece, it will be seen to be yellow. Immersion for a short time in hydrofluoric acid will, by dissolving away part of the layer, allow the characteristic yellow to be seen, as in the piece now handed round.

In the experiment described by Captain Abney in the March paper there appears to have been an unaccountable oversight, which, when pointed out, will, I think, be admitted. The trial of illuminating power was made by light passing through rather small holes in the side of a lantern. Now to find a reading distance with a clear medium like stained glass the opening in the lantern may be reduced until no larger than the flame, without affecting the result. With a diffusing substance like canary medium the smaller the opening the more the light is cut off, and the nearer the observer has to come to it to see with equal distinctness. The trials for protective power should have, therefore, been made in a similar manner at definite distances from the screens of the lantern. Instead of this, the glass and paper were laid upon a plate, and this exposed to the light of a candle flame; the conditions were therefore not comparative. It is, of course, obvious that when using a clear medium—the stained red—enlarging the area of the sides of the lantern would not have increased the illumination at any given spot (the book read from), but would have made a great difference to the diffusing medium—the yellow canary. Another, to me, unaccountable circumstance, is that Captain Abney should have found so much more protective power with the stained red glass than with the canary medium. I have examined several samples of the stained red—which, however, differed but very slightly—and find in each case that more photographic action passes than through canary medium. I have here a sort of negative, composed of three media side by side—a piece of stained red glass, a piece of canary medium, and one of ruby glass. Exposed either to lamplight or daylight the canary medium shows less image than the stained red, and the latter less than the ruby.

In addition to condemning the use of a yellow light Captain Abney stated that the use of a green glass only stopped those rays that were comparatively harmless; and in an article, about the same time, in the *Bulletin Belge*, said that he thought the recommendation to use it proceeded from a confusion of ideas. Now, if a piece of green glass, such as I have here, be examined in the spectroscope it will be seen that both ends of the spectrum are cut off, the blue is darkened, and the violet almost entirely cut off; the red rays are very much stopped, but the yellow passes pretty freely. When, therefore, such an accumulation of yellow is employed as to present a red appearance to the eye, the use of a green supplementary medium, by cutting off the red rays, restores the yellow character which, to most people certainly, is more agreeable and less irritating than red or orange, at the same time that it assists in more completely cutting rays off of some actinic power. In the lectures last delivered by Captain Abney before the Society of Arts it was recommended, when additional safety was required, to supplement stained red glass by a sheet of cobalt. I have here a double lantern, in one compartment of which I will use a stained red and a cobalt, and in the other a stained red and a green. It will be seen that much more light passes through the stained red and green than through the red and cobalt.

Taking the average of three observers—Mr. J. Cadett, Mr. T. Bolas, and Mr. W. K. Burton—it was found that the distance at which printing could be read with the light passing through the green supplement was within a trifle of half that required when the cobalt was used. This indicates a superior power of illumination of between three and four. I have here a printing-frame containing strips of the same green and cobalt glasses, each in union with the same stained red. I will now expose a plate behind these to the light, and develope together. It will be seen that the red and blue yield a powerful image, whilst the red and green give only a trace. As a supplement to stained red glass, therefore, the green allows three or four times as much working light to pass, and gives much more protection to the plate than the cobalt. The cobalt, in fact, acts by cutting off the useful yellow illuminating power, and renders the red deeper than before; whilst the green, by allowing the yellow rays to pass (and remember that the so-called stained red is really an accumulation of a yellow-transmitting medium) acts by cutting off some of the red and restoring a yellow character to the light. How much of the additional protection afforded by the green glass is due to the removal of the red, and how much to the cutting off of the other end of the spectrum, it is not necessary now to decide. I should think, however, that, in addition to the greater safety and the more luminosity, almost every one would prefer, as less disagreeable to work by, the yellowish light with the green supplement to the crimson with the cobalt.

As a method of working independent of coloured screens it has been recommended as a good working method to employ the comparatively white light of a candle or lamp, taking care to allow no rays to fall direct upon the plate, but to use only the light reflected from the ceiling and walls of the apartment. Those to whom any coloured light is offensive or objectionable may be glad to know of a method by which they can use a light of the same apparent character as the bare candle light, but of much greater safety. Here is a lantern containing two paraffine lamps—one furnished with stained red, and the other with a green glass. By allowing the light from these to fall upon a sheet of white cardboard, and stretching a sheet of white paper in front, a light is produced which is quite as white as that given by one of the lamps when used with no coloured glass, and illuminating the card in the same manner, and turned to such a height as to give equal illumination at a given distance from the screen. Mr. W. K. Burton, who kindly assisted me in making this experiment by taking the reading distance and exposing the plate at that same distance, considered, indeed, that the composite white light was in this case decidedly the whiter, less yellowish, of the two.

I will show you both, and I think you will agree with him. On developing the plate we found much less image on the plate exposed to the composite white light than on the other; and this, indeed, was to be expected, as both glasses used cut off the violet and ultra-violet rays—the most powerful photographic portion of the spectrum. I do not recommend this light for absolute safety; but upon a sensitive plate an exposure full square to the light for a minute, at a distance at which small print could be read, gave the merest trace of a mark—such as would not be recognised as fogging if there were no sharp edge to mark it. Now, there is never any necessity for giving a plate so much exposure to the developing light as this is equivalent to; and those who are particularly sensitive to coloured light may, by using obvious precautions, safely work with a light of this description.

From the experiment described with the ruby, the stained red, and the canary medium, the latter shows the most protective power; but, at the same time, it transmits less luminosity. When these conditions are equalised the comparative results show the least safety for the ruby; with the other two they are about equal.

With ruby glass, as stated a week or two back by Mr. A. Pringle, in describing the work of a sort of committee of investigation of well-known photographers in the north, the result was that canary medium showed less actinic effect than ruby glass in proportion to its luminosity. That stained red and a yellow material like canary medium should be about equal is only what might be expected from the consideration that stained red is, as has been pointed out, an accumulation of yellow, and yellow light passes largely through it. To compare red light with yellow light a medium of true red colour should be used, and then the experiment comes out in favour of the yellow medium. There is another consideration which also tells in favour of the yellow. The plates we use, and to see which we require the illumination of our dark rooms, are of a greenish-yellow; and the reading tests, to be accurate for the work, should have been on paper of a colour similar to that of the plate. These tests were, however, made on ordinary printed matter, and when—with the only observers with whom I had an opportunity of trying, Mr. J. Cadett and Mr. J. J. Briginshaw—a gelatine plate with writing upon it was substituted for the ordinary printed paper, it was found that it had to be brought relatively nearer to the red than to the yellow light before the writing could be deciphered.

If the balance of photographic and luminous effect of yellow and red light were equal we should choose the former, on account of its cooler, less irritating character, and the comparative absence of feeling of strain or fatigue, which most people, at all events, feel when compelled to pass any length of time in one as compared with the other. When we add to this the consideration that it is probable that some are now permanently and hopelessly injuring their eyesight in the employment of dry-plate manufacturers and of busy photographers, I think great responsibility rests upon those who would strive to perpetuate the present state of things.

The following propositions may now, I believe, be considered as established:—That the great difference in relative sensibility to different colours stated to exist in the two substances, bromide of silver in gelatine and the ordinary bromo-iodide bath plates, does not so exist; and that, therefore, the difference in the colour of the illuminating medium said to be required is a mistake. That yellow light gives more luminosity, in proportion to its effect upon the photographic plate, than real red light. That stained red glass owes much of its luminosity to the fact that it is an accumulation of yellow medium. That green glass cuts off both ends of the spectrum, and, therefore, in addition to rendering the light cooler, is a considerable protection. That green glass used as a supplement to stained red allows more illumination to pass than cobalt so used, and is much more strongly protective of the plate by obstructing photographic power. W. E. Debenham.

READY-SENSITISED PAPER. W. W. ROUCH AND Co., London.

WE have received samples of a new brand of ready-sensitised paper specially prepared for Messrs. Rouch and Co. It is fine in texture, possesses a smooth, even surface, and a high gloss, without the excessive tendency to crack which double albumenised paper exhibits. It prints rapidly and to a rich colour, and tones with readiness in any of the recognised toning baths. We have not yet had an opportunity of testing its keeping qualities, but they are said to be very good.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE last ordinary meeting of this Society for the present session took place on Tuesday last, the 10th inst., at 5A, Pall Mall East, in the Gallery of the Royal Society of Painters in Water Colours,—Mr. James Glaisher, F.R.S., President, in the chair. The minutes of the last meeting having been read and confirmed, the Chairman called upon

Mr. J. R. SAWYER to read his paper, entitled *Commercial Fabrics Suitable for Dark-Room Illumination*. Mr. Sawyer, after deprecating the warmth which had been evident in the discussion of the use of various colours for illuminating the dark room, remarked that Mr. W. S. Bird had some little time ago called attention to the discrepancies exhibited by the statements of different observers in regard to the chemical action of the spectrum, and had stated his opinion that there must be something wrong in their knowledge of the facts, and especially as the deductions from spectrum analysis differed so much from what was gathered by putting the matter to a practical test. Further inquiry was certainly desirable. He had tried to perform such experiments as would make it possible to give a verdict as to what was the best fabric to use for dark-room windows out of those easily obtainable commercially. He wished to avoid all controversial points In the first place great stress had been aid on the hurtful effects of deep red light, but surely those who brought this matter forward were in the habit of gazing fixedly at the red light itself, which was by no means necessary. He believed that no harm came from the colour of the light but only from the rapid transition from a bright to a dull light, and *vice versâ*, the ciliary muscles not acting instantaneously in contracting or expanding the pupil as we come from a weak to a strong light, and *vice versâ*, but allowing us to be for a time dazzled in the first instance and unable to see at all for a time in the second. He (Mr. Sawyer) had read a paper before the Society more than a year ago, in which he had explained the effect of photographing bands of different-coloured ribbons. He had that evening with him the bands of ribbons and the photographs, and it would be seen that a light yellow ribbon, although immensely more bright to the eye than an orange or a ruby one, gave less photographic effect. This formed a powerful argument in favour of yellow light for the dark room. He had tried the effect of the following fabrics and combinations of fabrics, namely, ruby fabric, orange, yellow, ruby orange and yellow, orange and yellow, and ruby and yellow in combination; also yellow paper treated with aurine varnish, white paper similarly treated, the above together; the same, but with two thicknesses of orange paper. Plates which would give 24 on the sensitometer had been exposed at a distance of eighteen inches from each for a space of five minutes, the source of light being a bright lamp. The plates were placed during exposure behind stencils indicating by letters the materials used, and were afterwards all developed in the same dish, being forced to the utmost. The various fabrics and combinations were shown in front of the lamp which had been used in the experiments, and also the plates which had been exposed. The yellow paper, which could be obtained from Messrs. Spalding and Hodge, Drury-lane, although permitting much more luminosity to pass, gave a less photographic impression than either ruby or orange. The fabrics in which there was aurine were safer still, but gave much less illuminating power. In the case of the last two media mentioned the plates were not acted upon at all. As to the practical arrangement of the dark-room window, he considered a good plan to be to divide it by horizontal lines into three equal portions, the upper third being covered with one thickness of whatever medium was used, the central with two, and the lower with three. The top portion could be swung open to admit white light when desired. A roller blind worked from the top would allow the light to be very perfectly regulated. He had tried the effects of using greens, but would not enter into the matter then, except to show a dark green which gave a very considerable photographic effect, whilst a lighter one, allowing much more visual light to pass, gave less photographic effect. He hoped the meeting would consider that his experiments had been carried out in a fair and practical manner, and that he had proved it was possible to have in the dark room such an amount of light as would ensure no damage being done to the eyes from abrupt transition to the outer light, and which yet would be safe.

Mr. W. E. DEBENHAM wished to show an improvement which he had made on his composite lamp. His lamp, it would be remembered, was so constructed, that on a sheet of white paper there is received the light filtered through a red glass, and also the light filtered through a green glass. The coloured light received on the white screen is reflected on to a piece of tissue paper, and, combining, makes a white light. He had substituted for the white reflector a yellow one, and in front of the white tissue paper had placed a piece of golden fabric. The light even then appeared as white as that obtained by reflecting the light from a lamp turned low, from a piece of white paper on to a piece of white tissue paper. Experiments made at "reaching distances" gave the following results:—With the last mentioned light a transparency was obtained in one minute. With the composite light and yellow reflector, but no golden fabric, a faint image only in a quarter of an hour. With the yellow reflector and golden fabric no image in an hour's exposure.

Mr. C. RAY WOODS wished to draw attention to a few points in Mr. Debenham's paper, read at the last meeting. [See page 377 in the present number]. He had compared the results obtained by using canary medium, orange paper, and stained red glass. He found the orange paper to have a slight advantage over the canary medium, and the stained red to have a great advantage over the orange glass. He considered that Mr. Debenham had failed to get the same stained red glass which Captain Abney had used, and which was flashed with silver on one side, and on the other with copper. The stained red used by Mr. Debenham was flashed only with silver and permitted ultra violet rays to pass, which accounted for Mr. Debenham having found a result of greater safety by using green glass in conjunction with it than when using cobalt glass, as recommended by Captain Abney. He considered that he was justified in using the expression "cathedral green," as it was once employed in the glass trade.

Mr. J. CADETT said he had carried out some experiments on the subject under discussion, in which he had been assisted by two or three other observers. He found that, as compared with theirs, his eyes were very insensitive to red light. Still, in the experiments which he had carried out, there had been evident a very little advantage in the case of stained red as compared with canary medium. In the case of those with eyes more sensitive to red the advantages had been more marked. This was to be remarked, however—that the advantage which the red colour displayed over the yellow was only noticeable in the case of a bright light. When we came to the use of a feeble light the state of affairs was renewed. He believed this fact was the cause of many of the discrepancies evident. Yellow light had a decided advantage over red in that it was better for the *general* illumination of a room. Thus, for example, it would be best to use yellow light in a drying room and red light when we came to examine plates individually for defects. He would say a few words regarding the spectroscopes. Some people were always tending to extremes, and a certain few had gone so far as to say that because the spectroscope could not alone determine the best medium to use for illuminating the dark room it was, therefore, entirely useless. He thought this a great mistake. To take an example: it was extraordinary how much blue light the spectroscope showed to pass through canary medium, thus indicating in what direction to work to make this light safer than it is by using some medium which will absorb the blue. Again: it was remarkable to compare two lights so apparently similar as those got through ruby glass and stained red, and to see how much blue was in the former whilst there was none in the latter. The spectroscope used with discretion would be found most useful.

Mr. DEBENHAM, in reply, said that he had found, on looking into the matter, that the stained red glass which he had been using was of two different kinds—one, that described by Mr. Woods, flashed on both sides, and the other, that flashed on one side only, and with silver. He had written to Messrs. Chance and Co. about the first-mentioned glass, and had learned from them that it was described as "flashed ruby, one side stained, yellow the other." It so happened he found that the red glass used in the experiment with the green and cobalt glass was of this description. He had one piece of even a deeper red than Captain Abney's was, and with this the result of his experiments was still the same. He got much less illuminating power with cobalt in conjunction with it than with green, yet far more photographic effect. Mr. Debenham wished to ask Mr. Cowan if his reported statement that seven thicknesses of his (Mr. Debenham's) stained red were not as deep in colour as one of Captain Abney's was correct.

Mr. A. COWAN replied that he alluded to Mr. Debenham's stained yellow.

Mr. DEBENHAM said that Mr. Sawyer had referred to the discrepancies in the results obtained by scientific experiments and practical workers; but he would ask if the method of proceeding in which the visual powers of various lights were first standardised, and the photographic power afterwards taken, was not as scientific as any, and more so than determination by the use of the spectroscope. Mr. Sawyer's experiments had proved very powerfully the advantages of yellow light over red, and would have done so still more emphatically had allowance been made for the visual intensity of the lights, the plates being in all cases put at such a point that the illuminating power was equal in each. With regard to Mr. Sawyer's experiments with green light, he was not aware that any one had suggested the use of a green fabric alone. He certainly had not. When using a green it was necessary to have a yellow green—not a blue one. He did not consider it advisable to speak of glass as cathedral green, as, even if that name were once used at all, it would refer to half-a dozen different shades.

Mr. L. WARNERKE objected to the use of aurine, as the colour faded. He had been experimenting on different fabrics, and considered by far the best to be one got by impregnating paper with chromate of lead.

Mr. W. PEEK thought red light had no injurious influences on the eyes. He considered Mr. Debenham's plan of testing at a reading distance not a good one, as it permitted the influence of individual peculiarity.

Mr. Sawyer, in reply to the various speakers, said that with regard to the scientific aspect of the matter it might be more correct to test the plates at the reading distance from the source of light; but with reference to the practical side of the question they had in their dark rooms windows fixed and sinks fixed, and, therefore, he considered the method which he had employed the most suitable. He hoped Mr. Debenham would not consider himself neglected because the question of greens had not been brought forward more fully. He himself considered that green in combination with other colours reduced illumination without introducing corresponding advantages. He was sorry to hear from Mr. Warnerke that the colour of aurine (a substance which had been recommended by Mr. J. Spiller) was not permanent, but if it were not there was an end of the matter. He felt great curiosity concerning Mr. Debenham's composite white light, and would like to have an opportunity of trying it.

The Chairman asked for a vote of thanks to Mr. Debenham and Mr. Sawyer. He did not object to hear differences of opinion expressed, but hoped that discussions would always be carried on in a scientific manner, each trying merely to bring forward the truth of matters and avoiding any controversial spirit. His own experience had been that it was impossible to get any two samples of glass precisely the same, and that no two people saw in precisely the same manner with regard to colour.

The vote of thanks having been accorded,

The Chairman called upon Mr. E. Dunmore for his paper, entitled *Silver Prints*. He then vacated the chair, which was filled by Captain W. de W. Abney.

Mr. Dunmore wished to give a few supplementary notes on Mr. Spiller's recent paper on the fading of prints. The word "permanency" might have a very elastic meaning. It might be used as indicating indestructibility or durability. He understood it in the last sense. Many prints of old days had remained good to this day, and certainly if we could follow the precise method by which these were produced we could again get permanent prints. Mr. Spiller had long ago recommended alkali in the fixing bath. He (Mr. Dunmore) had at that time himself been using carbonate of soda, but had given it up for the ammonia recommended by Mr. Spiller. He found, however, that this resulted in a slight powdery deposit on the prints. Mr. Dunmore then traced the production of a silver print through all the processes. He pointed out that the manufacture of the paper, on which much depended, was the only thing which was quite beyond the control of the photographer, although the albumenising was also so in most cases, as few photographers albumenised their own paper. He recommended a strong sensitising bath as tending to permanency. In talking of the printing and toning of paper he pointed out the double nature of the image, there being one image in an organic salt and another in metal. This accounted for the fact that a print from a thin negative would not take a rich tone. The image was almost entirely composed of the organic salt and the gold was not deposited on it. In toning a print from a clear negative they should stop the process before the half-tones are bleached. In fixing it is important to use freshly-mixed hypo. and to give a sufficient time for fixing, which might vary from ten to twenty minutes. After that, if the prints were thoroughly washed, he believed they would be permanent.

The Chairman admired the manner in which Mr. Dunmore had brought forward his observations, and especially considered his remarks concerning the double nature of the image to test by most valuable.

It was announced that Saturday, October 4th, would be the date of the opening *soirée* of the Exhibition of the Society, and that Thursday, September 25th, would be the last day on which pictures would be received. The following gentlemen had been elected as judges:—The President, Messrs. W. Bedford, W. F. Donkin, W. England, J. E. Mayall, W. Mayland, and Andrew Pringle.

The following gentlemen were unanimously elected as members of the Society:—Messrs. W. Van Sommer and S. G. B. Wallaston.

The meeting was then adjourned.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held at the House of the Society of Arts, John-street, Adelphi, on Thursday evening, the 5th instant,—Mr. F. York in the chair.

The Secretary having read the minutes of the last meeting,

The Chairman made a few remarks on the much-lamented death of an old member of the Society, Mr. H. Baden Pritchard.

Mr. E. W. Foxlee proposed that a letter of condolence be sent to Mr. Pritchard's widow, and Mr. W. Cobb seconded this motion.

The question of the annual trip of the Society was then discussed, and it was resolved that a meeting should be arranged for the last Saturday in July, unless Mr. Thornicroft could be persuaded to lend his steam launch to the Society for a day on the river, in which case the determination of the date would be left to that gentleman. It was suggested that the members of the Photographic Club be asked to join in the excursion.

A letter from the son of the Rev. F. F. Statham, the late lamented President of the Society, was then read.

The question of the presentation print to the members of the Society came up for discussion.

Mr. A. L. Henderson said he thought it would be satisfactory for all if a print from some negative of the late President were to form the presenta tion picture. He himself for one would like to have such a picture.

Mr. F. A. Bridge said that Mr. Henry Greenwood had been kind enough to present to the Society fifty prints of the Rev. F. F. Statham similar to those which had appeared in The British Journal of Photography, but on finer paper. He (Mr. Bridge) had unfortunately not brought them with him that night, but he would send them to the members.

On this intimation Mr. Henderson withdrew his proposal.

Mr. A. Cowan proposed that the presentation print be chosen from the competition pictures of the members, and further proposed that a committee be elected to choose the print.

The following gentlemen were then proposed and elected for the Committee:—Mr. F. York, Mr. W. M. Ashman, and Mr. W. K. Burton.

Mr. Bridge announced that the Council had determined to make the October meeting a special one to consider the future of the South London Photographic Society.

Some prints from paper negatives by Mr. Morgan, of Greenwich, were passed round. The general opinion was that no grains were visible in the prints. The paper for the negatives had been sensitised with gelatine emulsion.

The following question was then put before the meeting:—"What is the best developer for gelatine plates when copying engravings and line work?"

Mr. Henderson objected to the use of dry plates for such purposes. He would use wet collodion plates.

The Chairman pointed out that this was wide of the question, which asked for information regarding gelatine plates. He would himself use a ferrous oxalate developer.

Mr. Henderson suggested a slow emulsion.

Mr. Foxlee preferred the ferrous oxalate developer to any other.

Mr. W. K. Burton thought that if a sufficient exposure were given, and a pyro. developer were used strong in pyro. and restrainer but weak in ammonia, as dense a negative would result from sufficiently long development as with ferrous oxalate.

Mr. E. Cocking corroborated this statement.

The Chairman said that on account of the colour of the negative he would prefer carbonate of soda to ammonia. He used Mr. H. J. Newton's formula, and found excess of density rather than insufficiency to be his only difficulty.

Mr. Henderson differed from the Chairman on this point.

Mr. Foxlee said that in a line subject the great thing to do was to keep the black lines quite transparent.

Mr. W. Cobb thought that specially-prepared plates should be used.

Mr. Henderson asked the Chairman if the carbonate of soda did not cause frilling of the plates.

The Chairman replied that it did not if alum were used after development. It was curious that the plates took longer to fix when soda was used than when ammonia was employed.

Mr. W. Brooks would develope with ferrous oxalate, and would afterwards intensify with mercury.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Association, held on Thursday, the 5th instant, the chair was occupied by Mr. A. Mackie.

Mr. H. S. Starnes showed a dark slide made of tin plate. The advantages claimed for it were the small space it occupied and the cheapness with which it could be constructed. The plates were slid in at one end, which was then closed by a strip of velvet-coloured wood, leaving space only for the doors to slide on either side of it. A portion of the end of each door was bent over at a right angle to hold the strip of wood in place while the other door was open for exposure.

The Chairman considered that for a cheap dark slide it would be best to have a combination of wood and cardboard.

Mr. H. Moul said that it was most difficult to get card slides to work. Card was apt to buckle a little, and would then refuse to enter the groove at the end of the slide.

Mr. W. E. Debenham thought that the same objection held good with respect to sheet metal slides. He believed it would be better to make the frame somewhat thicker, so as to leave a space of about one-eighth of an inch between the front of the plate and the sliding door. The metal separating the plate from the door could then be folded, and at the end of the groove a little bevelled. This would allow the tin, although somewhat buckled, to find its way home.

The Chairman, referring to the screw-stoppered bottles now in common use for aërated drinks, said that he had requested the proprietors to make some bottles on the same system for chemical use, for which he thought they would be well adapted. He inquired whether any of the members could inform him of the nature of the material of which the bulk of the stopper was formed.

Some of the members thought that a gum resin or lac entered largely into the composition.

A short discussion took place upon the very divergent opinions that had recently been expressed with regard to a long washing of prints as an element of permanency.

Mr. Debenham believed that a long stay in the water was apt to cause fading—probably induced by the partial decomposition of the sizing of the paper. He had observed that prints left washing from Saturday to Monday commonly looked weaker than those which had only been in the water for a few hours.

A question from the box was read:—"Why does a very rapid plate take longer to develope when exposed with a drop shutter in the open air than the same plate given its proportionate exposure in the studio?"

Mr. A. L. Henderson said that this question assumed as a fact that which was not proved.

Mr. Debenham said that the conditions under which instantaneous outdoor photographs were taken were frequently, although not always, conditions favourable to the production of a weak image. In such a case if by time of development was meant time necessary to get up a certain amount of density, the matter was explained.

Mr. E. White was elected a member of the Association.

Correspondence.

June Meeting of the Photographic Society of France.—An Easy Method to Employ Eosine.—The Forthcoming Exhibition in Dublin.—Instantaneous Pictures by M. Braun.—M. Borg on Detaching Films.—Photocalque.—A Cheap Photographic Outfit.—Competition for Photographic Lenses Postponed until December, 1885.—Photographing Balloons.—M. Balagny's Films.—A Pocket Camera and Enlarging Apparatus.—Poitevin's Monument.

The Photographic Society of France held their monthly meeting on Friday, the 6th instant,—M. Davanne in the chair.

Among the correspondence which was read I gleaned the following:—That any commercial gelatino-bromide of silver plate can be rendered sensitive to the coloured rays by an immersion in a bath of eosine. It is preferable, however, says the writer, to put the eosine in direct contact with the emulsion. His bath is composed of—

Water	100 parts.
Eosine	30 ,,
Ammonia	10 ,,

If this simple immersion be all that is necessary it will greatly simplify the manufacture of eosine plates. The dye, when added to collodion or gelatino emulsion, causes great trouble by stains, in filtering, to the operator's clothes, hands, &c. I remember the difficulty I had five years ago, when I made plates for M. Ducos du Hauron, to induce an operator to work with the dyed emulsion, and one absolutely refused to have anything to do with it. The simple immersion will do away with all this, and will be a great boon to photographers who have to reproduce oil paintings or water-colour pictures, as they can dye the ordinary commercial plates themselves and use whatever purified photographic dye they may choose, according to the principal colours in the picture they have to reproduce. It is in the reproduction of polychromic pictures alone, in my opinion, that the introduction of aniline dyes will render service to photography. I have not yet seen any advantage in their use for landscape purposes.

I informed the members that I had received a letter from Mr. George Mansfield asking me to acquaint them that the Photographic Society of Ireland intended opening an exhibition in Dublin in November next, and that they should be happy to receive from France pictures and photographic apparatus and appliances. Any aid from their sister society would oblige.

The Chairman then replied that the Photographic Society of France would do all in their power, and ordered it to be inserted in the *Bulletin* of the Society.

M. F. Braun presented some very fine specimens of instantaneous photography, which were much admired.

M. Audra said that M. Borg, of Bordeaux, had intended to make a communication on the subject of a method by which the films of gelatino-bromide of silver negatives can be taken off their glass support without any previous preparation, such as the plate being collodionised, &c., &c. He (M. Audra) said he should have been most happy to have shown the members how to do it, but at the eleventh hour he had received a letter from M. Borg asking him not to communicate the secret. He could only show those present the results obtained by M. Borg. Loose films were then passed round, also films transferred to glass and paper, showing that the result was very satisfactory, and giving the idea that the "dodge" was a good one, making many regret the retractation of M. Borg (if it may be so called).

M. Cheysson was to make a communication on his process of *Photocalque*, as employed in government offices.

M. Davanne explained the process, which is too long to give here, but if found worthy will be inserted in full in The British Journal of Photography a little later on. M. Davanne then presented to the notice of the members a photographic outfit, given by a journal as a prize to yearly subscribers. He said that these apparatus gave a taste to youths to become amateurs, and was, so to say, a hot-bed for future members of their Society. The box contained everything necessary to make negatives, and positives were not lost sight of.

The gelatino-bromide plates of M. Hutinet and films of M. Bornstein were returned to the makers, as the Society is determined no longer to make a practice of giving their opinion upon the different commercial makes. The members are open to experiment privately upon any new preparation and give their opinions.

The Chairman informed the members that the competition opened by the Society and "Le Ministre de l'Instruction Publique" to obtain a new photographic lens has not gained the hoped-for result; therefore the committee proposed that the competition should be postponed until December, 1885. This was agreed to.

M. Balagny presented some negatives obtained on his gelatino-bromide of silver paper; also, some specimens of Tunisian ruins, &c. The tone of the proofs was very good. An inquiry being made, M. Balagny said that he had been inspired by the magnificent exhibit of Mr. Payne Jennings in the last Paris exhibition, and after many trials he has succeeded in obtaining a tone of picture similar to that gentleman's by means of a hot toning solution. Two solutions are prepared in advance:—

A

Water	1,000 parts.
Chloride of gold	1 part.

B

Water	1,000 parts.
Borax	30 ,,

B solution is heated to about 122° Fahr., and 200 parts of A added; the proofs are then plunged in and toned. They are then well washed and fixed in a hyposulphite of soda solution rendered alkaline by the addition of ammonia.

M. Vidal informed the members that it was the intention of the Chambre Syndicale de la Photographie to deliver a lecture on the 16th instant on the value of photography for reproducing works of art, to which all the members of the Photographic Society of France were respectfully invited.

M. Mosset presented some proofs of a balloon at different elevations, and showed the camera with which he had obtained the negatives—a quarter-plate camera, having in the place of the stand a small handle, and on the end of the tailboard a piece of wood by which the camera can be held to the shoulder like a gun. A "finder" is placed on the side of the camera in order to obtain the position of the balloon. M. Mosset employs a portrait lens, on the tube of which are marked or engraved different lines showing the position of the focus for a distance of 50, 100, 150, 200, or 300 metres. The shutter is on the guillotine principle. M. Mosset stated that the camera was aimed as soon as the start was accomplished, and when at a guess the balloon was about fifty metres from the earth the first picture was taken. The plate was then changed and the screw of the focus regulated, during which time the balloon had had time to rise another fifty metres, when a second "shot" was taken, and so on, until the balloon disappeared from view. The proofs were shown, but only the first or second were of interest, as a want of sharpness in the others was very conspicuous. The fault is in the lens employed being a portrait lens having a short focus. A long-focus rectilinear lens ought to be used. A larger image would result and a more perfect definition be obtained

M. Bardy presented a pocket camera made for M. Hutinet, the lens being the same as on M. Vidal's pocket camera, which I described in a former letter. The general opinion was that M. Vidal's pocket camera was far superior to the latter in weight and manufacture, the lens and dark shutter being the same. He (M. Bardy) then presented a new enlarging apparatus by M. Molteni for enlarging small negatives. The same instrument can be used as a magic lantern for parlour instruction and amusement. M. Bardy complimented the maker on having supplied a want, as he himself believed that ere long none but very small cameras would be used for landscape work. Many persons were working in that direction, and they had had cameras presented before them for that purpose. MM. Stebbing, Vidal, and Hutinet had all small cameras, but M. Molteni rendered such small instruments of service by inventing a cheap enlarging apparatus. The capabilities of the instrument were put to the test by projecting the images of some negatives upon a white ground. The uniformity of illumination was very apparent. The apparatus consists of an iron box, in the centre of which is a petroleum lamp. Behind the lamp is a concave silvered reflector, and before it is an achromatic condenser having the same concavity (towards the light) as the reflector. A camera with a movable bellows is adapted to the iron box. In front is placed any photographic lens which an operator may have at hand. The negative is introduced just in front of the condenser, and the rays are taken up by the front lens and then thrown upon the screen. The further the screen is from the apparatus the larger the image, and *vice versâ*. The great fault in this instrument is that only small negatives can be used. M. Hutinet's enlarging apparatus is superior from this point of view, as any size of negative can be employed.

M. Vidal, in the name of the committee for the erection of a monument to Poitevin, informed the members that the voluntary contributions amounted to 8,500*f.*, and that 1,500*f.* more were required to complete the sum demanded by the architect, which sum the committee hoped would be obtained, as several houses that had gained fortunes by Poitevin's invention had not yet come forward with one penny.

A pressing invitation is, therefore, made to the photographic community for funds. Any contribution from the readers of The British Journal of Photography will be thankfully acknowledged, and will be received by me in Paris or by the Editors in London. As the subscription is international, and many English photographers have already forwarded subscriptions, it would be well that their brethren who employ the carbon, photolithographic, and other permanent processes based upon the reaction of the chromic salts show their gratitude to the inventor of those processes, of whatever nation or country he may be.

25, *Rue des Apennins, Paris, June* 9, 1884. E. Stebbing, *Prof.*

THE PERMANENCY OF AURINE.

To the Editors.

Gentlemen,—In the paper read by me on Tuesday last before the Photographic Society of Great Britain upon *Commercial Fabrics for Dark-Room*

Illumination, and of which a report will doubtless appear in this Journal, I recommended the use of aurine, dissolved in negative varnish, to give a very non-actinic colour to paper and fabric for use in lanterns and dark-room illumination generally. In the short discussion that ensued Mr. Warnerke stated that he had found the aurine very fugitive in daylight. I have had really no experience with it in daylight, but it is perfectly stable with artificial light, and when introduced some years ago by Mr. Spiller was believed to be permanent under all conditions.

Upon inquiry I find that it is a permanent colour when used upon certain fabrics—silks and woollens, I believe, but not upon cotton goods—and according to Mr. Warnerke's experience not a permanent colour on paper. For all that it is exceedingly useful for artificial light work, and as I applied my aurine locked up with gums as a varnish I am not disposed without further trial to abandon it for daylight work. I shall expose one of my aurine screens to the full daylight and sunlight for the next two months, partially shielded, and with your permission report progress in the pages of your Journal.

I may mention that on receipt of a stamped and directed envelope I will send samples of the yellow fabric and yellow paper that I recommend, and which in my hands form a perfect and safe screen for making or developing the most sensitive plates. The paper is treated with a drying varnish to give it transparency.—I am, yours, &c., J. R. SAWYER.

Autotype Works, Ealing Dene, W.,

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN AND ITS REPORTS.

To the EDITORS.

GENTLEMEN,—Will you allow me space to make a few remarks upon Mr. Herbert B. Berkeley's letter on this subject in the last number of the Society's *Journal*, which has reached me today?

I gather from Mr. Berkeley's letter that some discussion must have taken place with regard to "errors and omissions" which occur in the reports contained in that *Journal*, as he alludes to a "conclusion" which has apparently been arrived at on another branch of the subject. As concerns errors and omissions, these may or may not be preventible; but they are, at least, open to correction when they do occur. I shall, therefore, confine myself to the "conclusion" which Mr. Berkeley now discusses.

Mr. Berkeley fails to see any logic in the conclusion that the suppression of the present reports in the weekly journals would constitute them, when they did appear, "stale news," and goes on to opine that it would be as reasonable to consider *the papers* when *they* appear "stale news." I venture to assert my own opinion—which coincides with those of many other members, though not with Mr. Berkeley's—that the papers as they now appear *do* form *unnecessarily* stale news, and are, moreover, in a certain sense, unnecessarily published; for the abstracts published, both of papers and discussions, by the weekly journals within three days of the meeting contain all that is necessary except to those who may be particularly interested in any special discussion. Such may refresh their memories or acquire more elaborate details when the Society's *Journal* appears—perhaps a month later.

The condensed reports, too, offer the advantage of being handy references by which the discrepancies arising between what actually occurs at a meeting and what appears in Mr. Berkeley's "full and corrected (presumably) report as having occurred." I thank him for the interpolated word, because it was a pretty general opinion when a recent case was partially discussed before the Society that the "weekly journals," three days after the event, gave a truer account of the matter called in question than did the Society's "full and corrected (presumably) report" *dated* (but not appearing) a month later. The charge fell through in consequence of what I may call a legal inaccuracy of description.

Mr. Berkeley's "best argument of all," based on the assumption of the meagreness and incorrectness of the weekly journals' reports, is the most singularly unfortunate he could have chosen; and I may conclude my references to his letter by stating, in reply to his last paragraph, that, as a member who attends the meetings and also as a "reader of the photographic press," I for one am anything but of the same opinion as himself upon these matters.—I am, yours, &c., A MEMBER.

June 9, 1884.

To the EDITORS.

GENTLEMEN,—I do not quite "see the logic" of Mr. Berkeley's letter in this month's number of the *Transactions* of the Society. That there is abundant room for reform in the management of the Society and its *Journal* no one will deny; but not in the manner suggested by Mr. Berkeley, namely, by giving the *Journal* a monopoly of the Society's reports, and keeping them from the public and country members for a month.

That there is a great deal of "staleness" about the Society's reports and about its whole proceedings is another undeniable fact which is solely and directly due to the Council's endeavours to perpetuate and render absolute the very course Mr. Berkeley now suggests.

It is a melancholy circumstance that the ordinary meetings of the representative (or what should be so more than in name) society of this country should be of so tame a character. The names of authors of papers and of those who regularly take part in the discussions may be very nearly counted on the fingers, and this in a society comprising four or five hundred members. This state of affairs is due to two causes, viz., the manner in which the ordinary meetings are conducted with a view of keeping them within the limit of one hour, and the present system of reporting. These I will take singly and offer a suggestion in connection with each.

One of the rules of the Society says that "the chair shall be vacated as soon after nine o'clock as may be convenient." The result is that in order to keep to this rule it is frequently necessary "to take a paper as read," or for the author to give an "abstract" of his communication. In the first case the paper is published in due course, and if the author be "nobody" there is an end of the matter. If, however, he be a person of importance, or of sufficient energy to demand it, a discussion ensues at the next or some subsequent meeting. In a recent instance the discussion took place *seven months* after the reading of the paper. In the second case the discussion may take place upon something that is entirely different from the paper actually published, as occurred a few months ago. Besides this the readers of papers are not unfrequently quite or nearly inaudible to all but those sitting on the Council benches, and the majority of the are consequently unable to take any part whatever in the discussion. Moreover, not knowing how much may have been keep back from the "abstract," many are unwilling to lay themselves open to the chance of being made ridiculous by the author informing them, in his reply, that "that is the opinion expressed in the paper, but for want of time omitted from the 'abstract.'"

It results from this that the discussions are too often perforce confined to those few who are in the habit of experimenting together or who may communicate their ideas one to another in private, and who, consequently, are in a position to know the contents of the unread paper. Thus Mr. A. delivers a brief *résumé* of a paper he has prepared and, upon his sitting down, a discussion is invited. After the members present have gazed stolidly before them for some time, Mr. B. rises and states that "by the courtesy of Mr. A. he has been permitted to witness some of his experiments, and is convinced that his deductions are quite correct." After another pause, Mr. C. (who is beyond the charmed circle) perhaps ventures to suggest that if such and such an experiment of Mr. A.'s has been conducted in a certain manner it is scarcely conclusive; when up bounces Mr. D. with the information that "he is in a position to state" that Mr. A. conducted the experiment referred to in a manner quite different from that suggested by Mr. C. If it be nine o'clock Mr. A. then replies generally, corroborating Mr. B. and Mr. D., and extinguishing Mr. C.; the Chairman declares the meeting adjourned, and a sigh of relief passes round the room as the members rise and form into groups to discuss matters of practical interest over a cheering cup of tea or coffee. If nine o'clock has not sufficiently approached when the subject is thus exhausted, Mr. E. utters a few mild platitudes which, by raising a discussion on a side wind, keeps the ball rolling until the meeting is abruptly adjourned at the usual time.

Now, if instead of, or in addition to, attaching so much importance to the rule I have quoted the Council would enforce another one—that which *suggests* that "communications intended to be read to the Society should be submitted to the Council one month in advance," and *directs* that "in no case can papers be read at any meeting which shall not have been received one week in advance," a different state of affairs would arise. It would then be easy to have the papers printed before the meeting, and printed copies distributed to the members present; or, better still, issued by the Secretary with the notice of meeting, when the members would arrive with the subject well studied, and fully prepared to enter into an interesting discussion. Then, indeed, the paper might be "taken as read" with actual advantage, and the time saved.

With regard to the reporting: the plan I have suggested would enable the papers read to be published in the weekly journals (and, for that matter, in the official organ also) the same week, which, as Mr. Berkeley points out, is the proper plan. If the editor and publishers of the Society's *Journal* cannot manage to get through their work in the same week, then by all means let the more energetic weekly journals, if they be willing, do for the members what the publication their subscriptions go to support cannot. If the *Journal* must cost upwards of £100 a year to the Society it need not also prove an injury to the members' interests.

Few of the members besides Mr. Berkeley would object to the publication of the papers a day or two after they are read and while the subject was still fresh, accompanied though they might be by the "meagre and incorrect" reports of which he complains. The "full and corrected" official report would still remain, if published only once a year, to supply the coveted fullness and accuracy.—I am, yours, &c.,

June 9, 1884. ONE WHO SELDOM MISSES A MEETING.

To the EDITORS.

GENTLEMEN,—Allow me to call your attention to Mr. H. B. Berkeley's letter in the present number of the Photograpic Society's *Journal*, and to add my complaint and suggestion.

I do not know whether he includes amongst his omissions the fact that no report is ever made in any of the journals of the proceedings after the Chairman has vacated the chair. This is the period when, in addition to the attractions of the refreshment table — always welcome after the intellectual drought of the previous hour—more luminous ideas are evolved and more really practical information passes from one to another in a single evening than, perhaps, in a complete session of the Society's formality.

To supply this would not, I imagine, cause you more trouble than to give the full and accurate report of each speaker's remarks *as delivered*, which seems to be so much desired. In this portion of the verbatim report, too, the speakers would be less likely to appear as if sometimes suffering from some temporary impediment of speech, or to have lost themselves in a sort of "Rosamond's bower" of verbiage than in the earlier proceedings. But we should have precision of diction, which is, after all, the main thing.—I am, yours, &c.,

June 9, 1884. A LOOKER-ON AND LISTENER.

[We have received two or three other letters on this subject all in much the same strain, but the above represent all that is to be said on the subject. The anonymous writer of an attack upon some of the leading members will understand why we take no notice of his communication. Our own word in the matter will be found in another column.—EDS.]

IODIDE OF SILVER IN EMULSION.

To the EDITORS.

GENTLEMEN,—I have been interested in your articles on *Iodide of Silver in Emulsion*, and have endeavoured to introduce a small quantity of the iodide by mixing with a bromide emulsion a small quantity of a separately-formed iodide emulsion. I succeed to a certain extent, but it seems to me there is great loss of silver in consequence of the coarseness of the iodide, much of which is filtered out. Can this be prevented?—I am, yours, &c.,

June 11, 1884. W. H. C.

Notes and Queries.

P. B. J. asks if the preparation of nitrous oxide is a matter of much difficulty.——In reply: There is no difficulty whatever in its preparation. All that is necessary is to place a quantity of crystals of nitrate of ammonia in a retort and apply heat. The gas is then evolved in great abundance and in a state of purity. Our correspondent is doubtless aware that this is the "laughing gas" of the lecture-room of a former period, its uses at present being mainly confined to anæsthetic purposes in connection with surgical operations of the minor class, such as the extraction of teeth.

C. O. E. A.—This correspondent wishes to know if the process of rendering photographs transparent by varnish after pasting them on glass, pigments being afterwards employed to colour them, is secured by patent.——In reply: There are more patents for this special department of photography than for any other; but, seeing that the process as described in the question of our correspondent was published more than once long previous to the first patent having been applied for, it follows that any one who is enamoured of this particular style of painting is quite at liberty to adopt it in everyday practice.

"WHAT is the readiest method for me to employ in converting a solution of nitrate of silver into metallic silver?—O. N. C."——In reply: Immerse strips or slips of clean copper, and the silver will immediately become precipitated upon it. The action that takes place is this:—The silver of the nitrate leaves the nitric acid with which it was previously combined, the acid in turn dissolving some of the copper. The precipitate is, therefore, metallic silver, and the solution becomes one of nitrate of copper, acquiring, of course, the greenish-blue colour characteristic of the presence of the copper salt. If the precipitate be washed and fused it will yield a button of pure metallic silver.

THOS. B. HUNT says:—"I do not quite understand what is meant by the spherical aberration of a lens, and would beg for a few words of explanation, thanking you doubly in advance if you will make such explanation capable of being comprehended by one who lays no claim to the possession of any scientific knowledge whatever."——In reply: We scarcely know what terms to employ in describing this phenomenon plainer than those already made use of, but we shall try. Spherical aberration means the inability of a lens to bring to a focus at one point all the rays of light which fall upon it and are transmitted. When the margin of the lens causes the focus of *their* rays to be nearer to the lens than those transmitted near the centre the aberration is *positive*. When, on the contrary, the marginal rays come to a focus at a greater distance than those of the centre, *negative* spherical aberration is indicated.

GEO. SANDERSON writes:—"One has sometimes proverbially to go far from home to hear home news. Some time ago I read in an American journal that the details of a recently-invented plate-coating machine, an invention by an Englishman, were to be published. Can you inform me if such an invention *has* been published or even completed, or must we regard it as as a *façon de parler?*"——In reply: We are not aware of publication having been yet made. We understand that certain mechanical details in connection with the machine probably referred to are in course of being perfected, and until this has been completed it would not be wise to bring it before the public. But from a perusal of our list of new patents in the present issue, it will be seen that a dry-plate manufacturer, Mr. B. J. Edwards, who, it is well known, prepares his plates by machinery, has secured a patent for the invention as, doubtless, worked in his own establishment. Seeing that Mr. Edwards has lodged a complete specification, our correspondent and those interested will have to wait only a short time until the specification is published.

J. H. B. says:—"I have a number of half-plate negatives of landscapes and street scenes from which I want, if possible, to produce lantern slides of the usual size. Can you oblige by advising, through the medium of your valuable Journal, the simplest method of effecting the reduction? I may mention that I exclusively use gelatine plates, and my negatives vary very much in density. I have looked through your ALMANACS and also the *Year-Books* for the past three or four years, but cannot find any way of reducing, although, of course, plenty of methods for enlarging are given."——In reply: In each of our ALMANACS there is invariably given a table of both enlargement *and reduction*, from which our correspondent ought to have deduced what he requires. But for his benefit, and that of any others who may be similarly situated, we shall endeavour to make the matter plain. Let the negative be erected in front of the camera and under such circumstances as to have a white or bright ground behind it at a distance of a few feet. This ground may either consist of a mirror reflecting the sky or a sheet of white cardboard upon which light falls. To the negative thus arranged the camera is pointed. If the camera be a small one having a lens to correspond the probability is that, if it be four feet away, the image will be too small; but in proportion as the camera is approached towards the negative so the dimensions on the ground glass increase. When in this manner the size desired has been obtained, all that is necessary is to insert a sensitive plate in the camera and expose. The photograph which results from this treatment is a transparency, and, if clear and bright, it will be adapted for exhibition in the lantern.

QUERIST.—A very good idea of the portable camera holder of Messrs. Oakley and Co. may be had by examining the diagram and reading the description of the same given on page 122 of our ALMANAC for this year. There is no patent restriction on its manufacture or employment.

WILSON NOBLE writes:—"I have a fancy for long-focus lenses, but I experience a certain difficulty in getting what I want. I use an $8\frac{1}{2} \times 6\frac{1}{2}$ camera, and for landscapes (I never take portraits; my friends find them so good when I do that they want too many copies) I use a 10×8 rapid rectilinear, eighteen inches focus, and a portable symmetrical, seven inches focus, and in preference use the latter without the front lens, thereby getting a lens of fourteen inches focus. What I want is a single combination lens of sixteen or seventeen inches focus—not to cover more than 10×8. A narrow-angle lens could be made with a large aperture, thereby having considerable rapidity; but in this I may be wrong."——In reply: Our correspondent should procure a single achromatic lens of the focus desired. It will not tax the powers of any working optician to grind a lens of this class, inasmuch as it is intended to include only a very small angle of view. The dimensions of the lens need only be small. One of this class, which we have mounted in a cell as a supplementary lens to screw into a whole-plate rapid symetrical mounting, has a diameter of an inch and five-eighths, its focus being sixteen inches. But our correspondent is wrong in supposing that a single lens of the focus he desires (seventeen inches) will bear a larger aperture than, or even so large as, the eighteen inches rapid rectilinear of which he is in possession. This being the case, he has nothing to gain, but everything to lose, by adopting the use of the single achromatic. True, with lenses of the combination class mentioned a flare spot not unfrequently appears in the centre of the plate; but this may be easily got rid of by adopting a supplementary mount, the length of which is a little greater than that of the original mount, which must on no account be tampered with. The separation of the lenses of an objective of the *genus* "rapid," by whomsoever manufactured, not unfrequently effects a total cure of the flaring propensity so common in this class of lens, although we have also done so by diminishing the distance between them.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHS REGISTERED.—

Edmund Eccles, Broad-street, Bury, Lancashire.—*Four Photographs of Sir Henry James, G.C., M.P.*

John William Watson, 2, Garden-street, Bury, Lancashire. — *Three Photographs of Sir Henry James, G.C., M.P.*

Frederick Argall, High Cross, Truro.—*Photograph of Dr. Wilkinson, Bishop of Truro, and Chaplain Rev. Maxwell-Lyte,* also *Rev. A. J. Mason, Vicar of Barking and Canon of Truro.*

D. T.—Keep the chloride of gold in solution as directed. Add a couple of drops of hydrochloric acid to each fifteen grains of gold.

L. S. A.—Without the permission of the authorities you will not be permitted to photograph in the grounds or buildings of the Health Exhibition.

THOS. J. WISTON.—If you refer to our volume for last year you will find that a very great deal has been published on the subject of photomicrography.

J. HUFF.—The prints in question are probably rolled with very heavy pressure on a highly-polished plate. The kind of paper will not account for the difference.

HY. YOUNG.—For ordinary carbon printing you cannot do better than employ the common bichromate of potash. There is, for this purpose, no advantage in using the more expensive salt—the bichromate of ammonia.

WILSON NOBLE.—The carbonate of potash used in combination with pyro. is far more prone to discolour and produce stains than any other form of alkali we have tried in development. It is energetic, but apparently little under control.

A. B. Z.—Soak the glass for a few hours in a strong solution of common potash; the films will then be easily removed. After that place the glass for a few hours in dilute sulphuric acid, and then dry and polish with tripoli as usual.

C. E. F. N.—Evidently the plate had not been cleaned before the emulsion was applied. This is the only suggestion we can offer. All solutions containing citric acid are liable to become mouldy by keeping. We have not noticed it with common alum and citric acid, but we have with chrome alum.

C. TUCKER.—The ordinary "white-lead" varnish of the oil shops, when diluted with methylated spirit, will, it is true, make a varnish that may be used for negatives. But such a varnish will certainly not prove a very durable one if the negatives are subjected to much rough usage, as they frequently are, in printing.

T. C. L.—The fault is in the manipulation and not in the chemicals. You have prolonged the development too much. Had you brought out the pictures quicker you would have avoided the staining. If in future you resort to such slow development, you must employ a much larger proportion of bromide to keep the shadows clear.

B. R. WILSON.—For enamelling silver prints you should employ a gelatine as free as possible from colour—one that is transparent. What you have been trying is quite unsuitable (though a very strong and good gelatine of its kind), because it is opaque and has a considerable amount of colour; hence you do not get so good results as those you so much admire.

W. M. J.—It is quite possible that the india-rubber has had an injurious action on the silver solution; indeed, from what you say, it is more than probable it has. Have you, for the water-tight top of the bath, used pure or only the vulcanised rubber? If the latter, the trouble is fully accounted for. The vulcanised rubber contains a large proportion of sulphur. This reacts on the silver solution, and in a short time renders it useless.

FALSTAFF.—One of the easiest methods of recovering silver from waste emulsions is to melt them and then stir in about four ounces of sulphuric acid to each pint. This will react upon the gelatine, and render it so limpid that the bromide of silver will quickly sink to the bottom. The liquid portion is then decanted, and the bromide rinsed in two or three changes of water. It is then collected and added to the other residues, or dried and sent direct to the refiner.

F. MUNCEES.—1. All will depend upon the size of the negative to be enlarged. If it be very small then you can employ the quarter-plate portrait lens; but if the size exceed (say) three inches and a-half, you had better employ your whole-plate rectilinear. Practical enlargers, as a rule, always employ a lens which is capable of taking a negative a size or two larger than the one to be enlarged.—2. If the lens be a good one it will not require much stopping down.—3. Keep the solutions separate, and mix as required.

A. VILLARS.—The trade mark is that of one of the foreign opticians. We have seen some lenses bearing it which were very good in quality. We do not see what difference it can make whether you purchase the lenses you require direct from the maker or through an agent. Of course they are all of the same quality. First-class opticians do not make two qualities of photographic lenses. The colour of the blinds must, in a great measure, depend upon the aspect of the studio. If you have to stop off direct sunshine you will require an opaque and dark material. A dark green is as good a colour as any. If only a north light, pale blue or white may be used.

T. LEYLAND.—From what we can see there is very little doubt that the stains on the prints are due to careless manipulation. This we judge from the general dirty appearance of the prints. They are covered on the back with finger-marks and other evidences of clumsiness.

RECEIVED.—Andrew Pringle; W. H. Harrison. Thanks.

A PHOTOGRAPHIC MEETING.—We learn through a correspondent that the *employés* in Mr. W. W. Winter's establishment at Derby made their first annual excursion to Dovedale a few days ago.

ANTWERP INTERNATIONAL EXHIBITION, 1885.—Messrs. C. B. Pare and Co., 126, London Wall, E.C., have been appointed official agents to represent British exhibitors and facilitate the transport of their exhibits to the Antwerp International Exhibition of 1885.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 18th inst., the subject for discussion will be—*On Printing-in Skies.* Saturday afternoon outing will be held at Waddon. Trains from London Bridge at 2.35. Finish at Carshalton.

GREENWICH OBSERVATORY.—The annual visitation took place on Saturday last, 8th inst., when Mr. W. H. M. Christie, the Astronomer-Royal, read his annual report. From this it appears that photography continues to occupy a prominent position in the work of the Observatory. Solar photographs were taken at Greenwich on 215 days during 1883, and on 125 of the remaining days. Indian photographs were available to fill the gaps; so that but twenty-five days of the whole year remain without solar photographs for measurement. For this special purpose a new photograph micrometer, by Messrs. Troughton and Simms, has been added to the apparatus of the Observatory during the year, which is capable of measuring photographs up to a foot in diameter. The continuous records kept by means of photography during many years past have been followed up during the past year; in fact, it would now be impossible to dispense with them. On the whole, photography may be said to have improved its position at Greenwich.

KEEPING QUALITIES OF GELATINE PLATES.—Mr. G. A. Addenbrooke says, in the *Journal of the Photographic Society*:—The following experience regarding the keeping qualities of gelatine plates may, perhaps, be worth noting:—A friend lately gave me an unopened packet by a well-known firm, stating positively that they were purchased before the summer of 1880—how long prior to that he could not remember. He says they were taken no particular care of, having lain for some months in a cupboard too damp to keep clothes in, and the remainder of the time in his dressing-table drawer. The first plate tested developed well but blistered all over in the fixing bath; the second was immersed in strong alum before fixing, and proved a very good negative, with the exception of an insensitive and fogged rim about a quarter-of-an-inch deep all round. The rapidity seemed about one-quarter less than the average rapid plate in the market now. I must confess I was not prepared to see the plates turn out as they did, and felt very gratified to find that so exquisitely delicate a thing as the sensitised gelatine film would keep so long a time with such slight precautions, if well prepared.

METEOROLOGICAL REPORT.

FILTERING AND CLARIFYING SOLUTIONS OF GELATINE.

It is frequently desirable, even if not absolutely necessary, to clarify a solution of gelatine; that is to say, to remove every trace of matter which tends to make it opalescent, and to render it bright and transparent. Now, while this is an easy matter when comparatively dilute solutions are in question, it becomes considerably more difficult when the viscidity or state of concentration is increased. As a familiar example of the first we may instance the culinary operation of clarifying jelly, which is performed by the joint agency of coagulated albumen and straining through flannel. But if the same means be applied to a thicker solution of gelatine—say, even of the strength of an ordinary emulsion—it would be found to be wholly inadequate.

Albumen is undoubtedly the best method by which the clarification can be effected, if only the coagulum itself can be removed from the gelatine after it has done its work. In passing from the soluble to the insoluble state under the action of heat, the albumen collects together, as it were, the excessively-minute particles of matter which are to be removed, and which from their minuteness are beyond removal by filtration. In a non-viscous liquid the coagulated albumen at once separates into clots, which are readily filtered out and the liquid left perfectly clear and bright. In a viscid solution like gelatine, however, the result is the formation of a sort of emulsion, the clots of coagulated matter being formed in a very minute state of division and held in suspension in the thick liquid, from which it is extremely difficult to remove them.

Some time ago a method was described in these columns in which albumen is mixed with the gelatine solution and the whole beaten into a froth, the temperature being kept just below the point of coagulation. The proper state of "froth" having been reached, the temperature is suddenly raised in order to effect the coagulation of the albumen, which, upon allowing the mixture to rest, rises to the surface in the form of a scum, carrying with it all impurities. This method, however, is only practicable on a large scale, and requires a considerable amount of skill and judgment in its execution.

Having recently had occasion to utilise the albumen method of treating gelatine we have endeavoured to substitute for the method just described the process of filtration under pressure, a very simple means of performing the operation being now available to every one in the apparatus described by Mr. C. Beckett Lloyd in our pages twelve months ago. But even filtration under pressure proves successful only under favourable conditions, which we shall describe.

In the first place, the albumen must not be added in excess of what is requisite, and must be most intimately mixed with the gelatine before it commences to coagulate; in other words, it must be added to the gelatine when the latter is at a comparatively low temperature, and, after thorough incorporation, the whole must be rapidly raised to the temperature of coagulation.

With regard to the quantity of albumen necessary: this will vary according to circumstances—that is, according to the quantity of foreign matter to be removed, and also, to some extent, to the hardness or otherwise of the gelatine. The white of one egg beaten up with four ounces of water to a stiff froth and allowed to subside is what we have employed, and of this mixture one drachm suffices for ten ounces of a twenty-grain solution of Coignet's "gold label" gelatine.

To apply the process the gelatine is first of all dissolved, and it should be dissolved in the largest quantity of water allowable. The albumen is then added at a temperature not exceeding 120° Fahr., and thoroughly mixed either by stirring or shaking. Have at hand a vessel of boiling water kept in a state of ebullition by suitable means. Into this the jar or beaker containing the gelatine and albumen is plunged, the stirring being kept up continuously. Albumen coagulates at a temperature considerably below that of boiling water; hence the heat available will be ample for the purpose. But a sufficient time must be allowed, as the process of coagulation is by no means instantaneous. Here is one of the chief causes of failure.

When the gelatine is first immersed in the boiler no immediate change will be apparent; but after stirring for some time, and when the temperature has reached 150° or 160° (perhaps before), the mixture will commence to turn opalescent, and will rapidly become quite opaque from the formation of finely-divided coagulum. As soon as the opalescence commences to appear cease stirring, and continue the action of the heat for at least another five minutes.

In very rare and favourable cases the gelatine solution will be nearly transparent, the albumen separating into distinct clots; but in the majority of instances it will be found to present more the appearance of a tolerably-fine emulsion, and will require very close and careful filtration to render it clear. For this purpose we have recourse to the "steam-exhaust" filtering arrangement described by Mr. Beckett Lloyd, or, rather, to a modification of it.

In its simplest form Mr. Lloyd's filter (figured on page 220 of our current Almanac) consists of a glass flask, to which a funnel is attached by means of a perforated cork. The flask being filled with steam the funnel, previously plugged with cotton wool, is fixed tightly in its neck, and as the steam condenses a vacuum is formed which draws through the filter any liquid that may be poured into the funnel. In the first place, the glass flask is not strong enough to sustain the pressure from outside when it reaches a certain point; it is not, in fact, adapted for slow filtration, and the plug of cotton wool is liable to clog on the one hand or filter imperfectly on the other. If a filter-paper suitably protected to prevent its breaking under the pressure be used air will gain access to the flask between the funnel and the filter, and so destroy the vacuum without effecting the desired end. For these reasons we have modified the arrangement in the following manner.

Instead of the flask a porcelain or earthenware jar or bottle is employed, taking care to select one with as narrow a neck as can be conveniently be employed. This is fitted with a good cork, thoroughly saturated, by boiling for some time, with paraffine. This is bored with two holes, through one of which is passed one leg of a "thistle-headed" funnel previously bent into ∩ form; through the other a tube bent at a right angle and fitted with a tap or cock, the joints being made secure by melting more paraffine on to them. The tube connected with the funnel reaches nearly to the bottom of the jar, the funnel itself reaching down to about the same height outside; the other tube, which may be of brass or copper, passes through the cork only.

In order to use this funnel a piece of thick felt, two thicknesses of filter paper "sandwiched" between muslin or calico to give strength, or any suitable medium, is tied over the "thistle" of the funnel, and the latter is dipped into the solution to be filtered contained in any suitable vessel—a cup or beaker, for instance—of such depth that it will reach to the bottom, and so take up all the liquid. The second tube is now connected with a small glass flask containing water, which is brought to the boiling point, sending a stream of steam into the large jar, and thence through the funnel into the liquid to be filtered. When the steam is seen to be passing freely into the liquid the cock on the bent tube is closed, the heat removed from the water flask, and, as the contents of the jar cool, a vacuum arises which causes the liquid to be filtered to pass through the filter and into the jar. Upon the perfection of the joints depends the degree of thoroughness to which the filtration may be carried. If only moderately good an immense pressure is brought to bear upon the liquid, sufficient to force it through almost any medium that is at all pervious.

Another application of this method of close filtration is in connection with the cure of "pits." So far as we have been able to ascertain with a number of samples of gelatine liable to the fault, it proves an infallible cure. It must be applied to the gelatine, however, and not to the emulsion, otherwise a large portion of the silver salts will be removed.

PRACTICAL DETAILS OF ALBUMENISING PAPER.

Redeeming the promise we made last week, we shall now proceed to describe the working details of the preparation of albumenised paper.

The first thing is to decide how much albumen has to be prepared to coat the quantity of paper required. As a guide, it may be mentioned that a ream of paper will consume from a gallon and a-half to two gallons of albumen; and, as one egg yields from three-quarters of an ounce to an ounce of albumen, according to its size, it is easy to arrive at the number that will be required to coat a given quantity of paper, bearing in mind that more than is actually consumed by the paper must be prepared—sufficient to well cover the bottom of the dish when the last sheet is floated. Thus, a couple of quires of paper (a convenient quantity for an amateur to prepare at a time) will take something like a quart of albumen; this, on an average, will be obtained from about fifty eggs. If the paper be coated in the whole sheet of course considerably more than this will be necessary; but, for the nonce, we shall assume that the paper will be prepared in quarter sheets, as that will be the most convenient size for the novice to commence with.

Fresh white of eggs can now be purchased in any quantity, the egg merchants finding it to their advantage to break the eggs and sell the albumen and yolks separately, as there is a large demand for both, but for different purposes—the former for albumenising paper for photographic purposes, and the latter in the preparation of kid leather for the manufacture of gloves. Therefore, when the albumen can be conveniently purchased separately it will be found more economical. However, we shall assume that this cannot be done, and therefore the eggs must be broken by the operator himself. Here some little dexterity is required in order to avoid the yolk getting mixed with the whites. The best plan is to break the egg by giving it a smart tap on the edge of the cup, and then drain the albumen into it, retaining the yolk in the shell. By draining the white from each egg first into a cup, the yolk, if it be accidentally broken, does not get mixed with the bulk of the albumen. The yolks can, of course, be transferred to the culinary department, where they will doubtless prove acceptable.

It is generally recommended, in breaking the eggs, to separate the germ from the albumen, but this is never done in actual practice. With regard to the kind of eggs to be used: good ordinary French eggs will answer quite well, and they will be found practicably as good as the more expensive "new laid." The requisite quantity of albumen being obtained it is well stirred up, and to each quart three hundred grains of chloride of ammonium, dissolved in the smallest possible quantity of water, is added. The whole must now be converted into a perfect froth. Unless this part of the operation be very perfectly performed it will be quite impossible to ensure a perfect coating. Professional albumenisers usually employ an American churn for this purpose; but, on a small scale, the domestic egg whisk borrowed from the kitchen will answer quite as well. The whisking must be continued until the vessel containing the albumen can be inverted for a minute or two without any of the albumen draining out. The vessel is then placed away in a cool place for three or four days according to the temperature, to allow the albumen to subside. By this time it will have become very limpid. If the albumen be kept in a cool place, and the eggs be tolerably fresh when broken, it will keep the above length of time without fear of decomposition. It could be used after a day's keeping, but it would be next to impossible to obtain a coating perfectly free from streakiness.

Some albumenisers, we believe, keep the albumen for a much longer period than that named—or until it has become quite putrid—before use, as then it is more easy to manipulate, and produces a finer gloss. We have been given to understand that dried blood albumen is sometimes added to thicken that obtained from the eggs, so as to obtain a still higher surface. However, the employment of decomposed and blood albumen was spoken of last week, and it need not be further alluded to here, the object of the present article being—assuming the paper such as that supplied some dozen years or so ago cannot now be purchased—to show how anyone may prepare it for himself. The proportion of chloride recommended above will give seven grains and a-half to the ounce of albumen, and will, therefore, be suitable for a sixty-grain sensitising bath similar to the one in vogue about that time.

Leaving the subject of the albumen for a few minutes, it will be well to direct attention to the paper itself. It is tolerably well known that the two sides of a sheet of paper are different, one being very smooth, while the other possesses a certain amount of roughness, due to the web upon which it was dried in its manufacture. Of course it is the smoother side which is to be albumenised. As the reams are received from the mill the smoother side is always packed in the same direction; but when the ream is broken, and the paper sold in small quantities, it frequently gets mixed. Therefore it is necessary to examine each sheet separately, and in cutting it up—supposing it is to be prepared in less than the whole sheet—to take the precaution that the smoother surface is arranged all one way, so that no mistake need be made in floating the wrong side on the albumen.

The albumen having stood the requisite time, it is now carefully strained; a fine cambric handkerchief will form a good medium for the purpose. After straining, the most careful albumenisers filter the albumen through a sponge; but this is scarcely necessary if the cambric be close in texture, and the albumen has been carefully decanted without disturbing the sediment. It is now poured into a dish of a suitable size, avoiding the formation of air-bubbles as much as possible. After standing for a short time, to allow any minute ones that may be accidentally formed to come to the top, the albumen is carefully skimmed by drawing a piece of blotting-paper along its surface. It is now ready to receive the paper.

In floating the paper some little dexterity is required to avoid bubbles, and many operators have different plans of placing it upon the albumen. Some bend the paper in a curve and apply the middle first, and then gently lower the two ends. Others, holding it by opposite corners (diagonally), bend it, and apply first one of the free corners, gently lowering it to the other, and finally lower the two corners by which it is held. Many apply the paper in this way, and it is the plan we prefer:—Holding the sheet by its two ends they place one on the surface of the albumen at one end of the dish and gently lower the remainder. By this method any air-bubbles, should they be accidentally formed, will be driven towards the end of the sheet, where they can easily be forced out by gently tapping the back of the paper with the tips of the fingers; whereas if any be formed when the middle of the sheet is applied first they are not so easily noticed, or expelled when they are.

When the paper is first applied—particularly if it be very dry—it will probably curl up and leave the albumen at the edges, but it will speedily flatten out again. It must not, however, be removed until it lies uniformly flat; otherwise the coating will prove unequal in thickness when dry. In practice it is advantageous to employ two dishes, and it will then be found that by the time the second sheet is floated the first one will have become flat and ready for removal, and thus time will be considerably economised. If the paper be floated for too long a time the albumen will sink deeply into it, and thus, to some extent, prevent a high gloss being obtained.

As there are many little manipulatory details of importance in connection with the removal of the paper from the albumen, and the drying of it, which pressure on our space precludes our entering into now; and, as we are anxious to make the instructions as explicit as possible, we defer until next week the final portion of the subject.

THE INFLUENCE OF A LENS SUNSHADE.

It is always a safe practice to prevent, by means of a suitable hood, any more light from falling upon a lens than that which comes from the subject to the reproduction of which the photograph is to be confined. Anything beyond this is of no utility, and, under certain circumstances, may prove mischievous.

It cannot have escaped the notice of our readers that whereas in front of some lenses the mount projects so far as to form quite a deep hood, in others the lenses are brought up to the end of the tube in which they are contained, and no more of the tube remains projecting than is barely sufficient to shield the convex surface of the glass, and protect it from being scratched if laid down upon its end. Now, in such a case as this, it follows that the lens is totally devoid of the protecting agency of the hood as a sunshade, by which is here understood any means to screen the lens from a bright sky.

Having observed on one occasion that two negatives of the same subject—the lens in one case having been carefully screened, while in the other it was not—were alike equal in brilliancy, we have been led to bestow some attention upon the subject of the uses of sunshades.

The function of the hood, in addition to its forming a place for the cap, is to prevent more light from entering the lens than is requisite in forming the picture. There is an idea prevalent that if the light from the sky strike the lens it will, in some measure, tend to fog the photograph. In ascertaining the precise degree of truth contained in this surmise it is necessary to take an extreme case, and we have done so by directing the camera towards a view possessing an abundance of deep shadows as well as high lights, removing, for the purpose of our experiment, the hood of the lens and permitting the direct rays of the sun to fall upon its surface. The lens employed upon the occasion to which we here refer was one of the well-known "rapid" type. This, it will be admitted, was, indeed, an extreme case.

Having first of all attached to the front of the lens a movable skyshade, which was "set" in such a manner as to cut off all that was not intended to be included in the photograph, we examined the image on the ground glass. While engaged in doing this a friend, by arrangement, turned up the skyshade so as to permit a beam of direct sunlight to fall upon the lens. There was a slightly appreciable increase in the illumination of the foreground shadows, showing that the direct sunlight upon the front lens had exercised some degree of agency of an adverse character. To ascertain the immediate cause of this increase in illumination, the ground glass was removed and the appearance of the lens observed, when the eye was placed in the line of light reflected from the lens. The impact of the solar beam did not appear to affect the instrument itself in the slightest degree; neither was there any reflection from the edge of the lens, which was not only well blackened with varnish, but had an annulus of blackened brass inserted in the cell, so as to cover up the margin of the lens completely. But from the fixed central stop in the lens, composed of an unnecessarily thick pair of plates of brass, and upon the edge of which the solar beams impinged, there was a reflection of a decided description, and it was this that caused the illumination of the shadows of which we have spoken.

When the lens had been unscrewed from the camera and special precautions taken to prevent this reflection from the edge of the fixed stop, by painting the brasswork with a very deep, non-reflective black varnish, the cure of the evil was effected. There was then no difference perceptible between two negatives, one of which was taken with the lens entirely shielded from the sun's rays, the other with the rays allowed to enter obliquely as already described. Of course, in no case was the light of the sun permitted to pass through the lens on to the plate; all we aimed at was to secure its transmission at an angle so oblique as only to impinge upon and illuminate the sides of the mount.

The whole of the evil attributable to the impact of strong light upon the anterior surface of a lens such as we have been speaking of is not caused by any internal or other reflection of an optical nature, but arises solely from the mount. To demonstrate this we arranged a lens in relation to the direct solar rays, so as to give the maximum of reflection or flare. Then, without disturbing the camera, we unscrewed both lenses from the mount, which we replaced by two boards that might be represented by the top and bottom of a cigar-box, and, in truth, formed the arrangement in this case. Here, then, we had the lenses separated from each other to the same extent as in the original mount. They were inserted in apertures made in the top and bottom of the box directly opposite each other, without the slightest chance of any reflection being caused from the sides of the box. In this experiment, no matter to what extent or at what angle the sun's rays were permitted to fall upon the front lens—so long as they were not permitted to have access to the second—none of such rays seemed to have the slightest influence upon the image on the ground glass, which was quite bright and sharp, no matter whether the solar rays fell upon the anterior lens or were prevented from so doing.

There are, however, circumstances in which this immunity from fogging will not be secured. Unless the anterior lens be not only polished in a most perfect manner, but is also quite clean at the time of the trial, it will become not alone a transmitter of light but a radiant that diffuses in every direction, in a greater or less degree, the light falling upon the surface. It is under these circumstances that fogging is induced by the impact of light upon the front surface of a combination.

From what has been said it follows that, if a lens be well polished and properly mounted, there exists no necessity whatever for having a prolongation of its mount in front; for a hood does not in the slightest measure diminish the chances of fogging when the sky is bright, or the direct rays of the sun are absorbed by the anterior element of the combination.

A NEW GELATINOUS MATERIAL.

The uses to which gelatine and similar substances are put in photography are so manifold and so important that an account of any addition to the list naturally possesses great interest. We gave details last week, gleaned from Mr. Stanford's paper read before the Society of Arts, of the connection between seaweed and the important elements bromine and iodine; and today we purpose bringing before our readers particulars which suggest a practical outcome in photographic directions of that gentleman's investigations upon the gelatinous materials to be obtained from seaweed.

Many inquiries have of late been made about gelatinous substances from Eastern sources, but of whose actual origin little seems to be known, the so-called "Japanese isinglass," sometimes termed "gelose," being one of them. This remarkable substance which has been successfully tried in emulsion-making, is extracted from a species of seaweed to be found on our coasts, though not very readily, the particular plants to which Mr. Stanford directed his attention being of common occurrence, and found in practically illimitable quantity. The well-known orders of *Fuci*, familiar to a dwellers by the shore as "wrack," "bladder-wrack," &c., at one time furnished all the seaweed used for making kelp; but they are now entirely neglected, and the *Laminaria*—the red weeds found growing only under water, though often torn up by storms and cast ashore as "tangle"—are employed in their stead.

The extraction of iodine is the chief object of the collection of this weed, but this new gelatine is now proposed as an equally important product by Mr. Stanford, who has devoted a lifetime to the investigation of the weeds and their economic applications.

Before describing its properties in detail it may be well to refer to the properties of the gelose alluded to, as tabulated in comparison with other similar substances by that gentleman. He finds 1,000 parts of water to require of—

	Parts.	Proportion.	Melting Point.
Gelose	4	1	90° F.
Gelideum corneum	8	2	90° „
Irish moss...........	30	7·5	80° „
Isinglass	32	8	70° „
Gelatine..............	32	8	60° „
Carragheenin........	36	9	70° „
Agar-agar...........	60	15	90° „

Gelatine is a very wide term, but the table gives, no doubt, an average.

Coming, now, to the mode of procuring this new material, it may be briefly described as the gelatinous matter mixed wiih cellulose that remains after the weed has been maccrated with water to remove the salts, and the name "algin" is proposed to be given to it. Algin is a combination of calcium magnesium and sodium, with a new acid to be called "alginic acid," and it is extracted by macerating the plant in carbonate of soda, and by a peculiar process separating the cellulose. The liquid obtained is precipitated by hydrochloric or sulphuric acid. The alginic acid separates, and is washed and pressed into a compact cake, in which state it may be sent into the market, or it may be easily bleached first. It may also be saturated with soda and sent out as alginate of soda. It is thus seen that it possesses the great advantage of being a strictly-defined chemical product, which might be expected to be made by purification of uniform character. We do not forget that the same remark was made of gelatine as opposed to pyroxyline, though it was quickly discovered that no such expectation could be realised.

With regard to the properties of sodium alginate: it will be seen that they are very remarkable, and, either as a medium for emulsion or as a mounting material, the substance evidently deserves a thorough trial. It forms a thick solution when of two per cent. strength, and when above five per cent. it will not pour. Its viscosity is extraordinary. It was compared with well-boiled wheat starch, and with gum arabic in an ordinary viscometer tube. The strengths employed were as follow. It was found impossible to make the algin run at all over the strength employed:—

			Seconds.	
Gum arabic solution...	25 per cent.	took	75	= 1 in 3,
Wheat starch...........	1·5	„	25	= 1 in 8,
Algin	1·25	„	140	= 1 in 112,

so that algin has fourteen times the viscosity of starch and thirty-seven times that of gum arabic. The evaporation of the algin so as to form sheets is performed in a similar manner to that adopted with glue, and the sheets are almost colourless and very flexible. It possesses several remarkable properties which distinguish it from all other known substances.

Algin, or sodium alginate, is precipitated among other things by alcohol and collodion, but not by ether. Many acids, silver, and other metallic salts precipitate it; alkalies, pyrogallic acid, bromine, iodine, or chlorine water, &c., do not precipitate it, nor does tartar emetic, thus being distinguished from gelatine, and also by not being acted upon by tannin. It most resembles albumen, but is not coagulated by heat; and, unlike gelose, it does not gelatinise on cooling. In this particular it is more like tragacanth—a much-neglected mounting material. It is not dissolved by boiling water.

Among its other properties is a power of forming a compound with aluminium, which is soluble in ammonia, and forms when dry an insoluble varnish. With chromium it forms a compound soluble in cold water, which is rendered insoluble by boiling. It behaves in a similar manner to gelatine when mixed with bichromate, becoming insoluble under the influence of light. The silver alginate is stated to darken very rapidly under exposure to light. Finally: Mr. Stanford says—"It forms a singular compound with shellac, both being soluble in ammonia. It is a tough sheet, which can be rendered quite insoluble by passing it through an acid bath."

Thus, as a possible substitute for and improvement upon gelatine for emulsion, for mounting, sizing, varnishing, and other purposes, algin or sodium alginate promises to be a most interesting and valuable addition to the list of photographic chemicals.

Our friend Dr. Liesegang recommends in another column, as a protection to the surface of collodio-chloride prints, the application of an extract of *Semen psyllii*. As many of our readers may be ignorant of the nature of this substance, and probably cut off from sources of reference, we may say for their benefit that the seed referred to is that of *Psyllium pulicaria*, belonging to the order of *Plantageneæ*, and commonly known as *Fleawort*. The seeds are remarkable for their mucilaginous character, and have been used as a substitute for linseed and marsh-mallow in the concoction of demulcent potions. The extract or decoction is also used as a substitute for starch in the getting up of some of the finer forms of linens and muslins.

Few people are unacquainted with the difficulty and trouble attendant upon the want of adhesion of labels to metal and to glass bottles where exposed to variety of temperatures; hence any new mode of meeting the difficulty will be useful. For glass bottles a solution of chrome alum and gelatine is, perhaps, as good a damp-resisting mountant as any. Metal always presents difficulty, especially when exposed to damp; but, according to a foreign contemporary, it can be overcome by the use of albumen for the purpose. White of egg well beaten up is diluted with its own bulk of water and applied with a brush to the surface to be united; and then, before it is dry, a hot iron is passed over the paper so as to coagulate the albumen. It is also suggested that, by means of successive layers of paper and albumen, waterproof boxes, &c., may be formed.

Visitors to Padua are familiar with the church of St. Antonio (the Santo), where are to be found some of the most beautiful *bas-reliefs* and statues by Donatello—marvels of delicacy and perfection of execution, forming most attractive objects to the student. They are, however, in many instances, placed most awkwardly for obtaining sketches, and a demand for photographs has often been made. According to the *Athenæum*, well-known Italian photographers have been applied to for photographs of the many objects of interest in the Santo, but have been met with the invariable response that neither their position nor the light they receive permits their being executed with any chance of success. The result has been that, so important are these bronzes considered in the world of art, they have been repeated in plaster, for the purpose of the plaster cast being photographed. This has been done very successfully, and a series of twenty-five *photogravures* have been obtained which exhibit the qualities of the original in a high degree. We are, however, quite one with the *Athenæum*, which, speaking of a particular subject, says:—"Supposing, now, that this altar front was set in a fair light before a photographic camera, although in the reproduction some of the detail would be lost, on account of the varying colouration, yet the gain in depth of tone would more than counterbalance the trifling loss of some minor incidents."

The names of Swan and of Edison are inseparably connected with the electric light, and more particularly with the incandescence forms which may be said to have been brought to perfection by these gentlemen. It is stated, however, that Mr. Edison is changing his views upon the advantage of the incandescence system, and is about to introduce an arc light.

We would call the attention of our readers to a most interesting extract [see page 395] from a lecture by Dr. Gill, whose photographic work at the Cape in connection with the great comet of 1882 will, no doubt, be fresh in our readers' memories. The growing—indeed, we may say the paramount—importance of photography in astronomical operations is shown in a strong yet lucid manner, and the utmost emphasis is laid upon the actual necessity for its employment and the important place it will occupy in the future. So much, however, have photographic processes advanced that we are strongly of opinion that, at no distant date, trained specialists in photography will be needed in addition to the

SUPPLEMENT TO THE BRITISH JOURNAL OF PHOTOGRAPHY, JUNE 20TH 1884.

J. W. SWAN.

INK-PHOTO, SPRAGUE & Co LONDON.

ordinary astronomical staff to obtain the highest results of which photography is capable. The time must come when training in photography will be almost as important as in chemistry, and steps will have to be taken for establishing a centre of teaching.

Cadmium is filling a new function in forming, in the metallic state, one constituent of a very fusible alloy. Professor Guthrie, in the course of an investigation upon the behaviour of salts in solution, carried his experiments into the region of metals in a state of fusion, and devised one alloy which melts at an extraordinarily low temperature—160° Fahr. This, it will be seen, is far below the temperature of boiling water, and, if the alloy were available otherwise, there would be no obstacle in the way of obtaining a mould from a gelatine relief. It is composed as follows:—47·38 parts of bismuth, 13·29 of cadmium, 19·36 of lead, and 19·97 of tin. It would, however, be rather an expensive metal when required in quantity, otherwise many very useful applications might be found for it in photographic processes.

MR. J. W. SWAN.

There are few names in contemporary photographic history that are more familiar or have been longer known to the readers of this Journal than that of Mr. J. W. Swan, the subject of our illustration this week. First known in connection with the late Mr. John Mawson, of Newcastle-on-Tyne, as a member of the firm of photographic chemists in that city whose collodion and other products have gained for them a reputation wherever photography is practised, Mr. Swan upwards of twenty years ago devoted his energies specially to the solution of one of the problems of the day, and the result of his devotion to progressive photographic research was the publication of the first practical carbon printing process.

Utilising the discoveries of Poitevin, Mungo Ponton, and others, and working on somewhat the same lines as Fargier, in France, he was the first to bring carbon printing within the domain of daily practice, by not only recognising the necessity for, but actually carrying out the development of, the "tissue" from the back, and thus rendering it possible to secure natural half-tone where hitherto it had been only possible to secure black and white. Swan's patent, taken out in 1864, formed the basis of the present process known as "autotype," and the company still in existence bearing that name was founded for the purpose of purchasing his patent.

Since that period Mr. Swan has lent his energies to many applications of chromated gelatine and mechanical printing processes, as well as to other branches of photography. He was one of the earliest to recognise the value of gelatine dry plates, and his firm was among the first to place them commercially before the public.

To the outside public—that is, to the non-photographic public—the name of Swan is as familiar as it is to photographers, through his connection with electric lighting. Swan's "incandescent lamp," though an outcome of the most modern advances in electrical science, is no new idea to its inventor, as the first publication of the principle of incandescent lighting came from Mr. Swan as far back, we believe, as 1847 or 1848. But at that time it was unfortunately impossible to carry out the idea, owing to deficiencies in the mechanical appliances as well as in the scientific knowledge of the day; but the introduction and rapid development of dynamo electric machines, and the consequent cheapening of the production of electricity, with the improved methods of exhausting the globes of the lamps, no less than the great rage for electric lighting, combined to render the Swan mode of lighting a great success.

Mr. Swan is a Fellow of the Chemical Society and of the Institute of Chemists; a member of the Society of Telegraph Engineers and of the Society of Chemical Industry. He was President of the Newcastle Chemical Society in 1882. Last year, in recognition of his services in the interests of science, the University of Durham conferred upon Mr. Swan the honorary degree of M.A.

Our portrait is from a photograph by Mr. E. D. Lavender, of Bromley.

LIME-LIGHT EXPLOSIONS AND THEIR PREVENTION.

In repeating the experiments of my last paper with oxyhydrogen gas instead of ether, I did not think it necessary to record the whole of them, but merely a few of the most distinctive.

The results obtained were different from what I expected, for I have often noticed that a flame of ether burning at the orifice of a jet is easily blown out by the breath or by a puff of wind; whereas a flame of hydrogen seems to cleave to the tip of the jet and is not so readily extinguished. I expected, therefore, to find that the oxyhydrogen would be more difficult to deal with than the ethoxo gas, and would force its way through a longer safety tube. The contrary, however, appears to be the case, as the following experiments will show:—

No. 1. A balloon filled with explosive oxyhydrogen gas and attached to the tap of the jet. The flame burns at the orifice of the jet as long as the pressure keeps up, but as soon as the sides of the balloon collapse it passes back with a loud report.

No. 2. Same as the last experiment, but with a piece of cane an inch long attached to the tap of the jet. Flame stops at the cane and does not enter the balloon.

No. 3. Same as No. 2, but balloon filled with an explosive mixture of *coal gas* and oxygen instead of oxyhydrogen. Flame passes through the cane and bursts the balloon.

No. 4. A safety tube half-an-inch in diameter and half-an-inch long, filled with tin filings screened as before described, and placed in the *front* part of the jet immediately below the mixing chamber. Balloon filled with coal gas and oxygen, as in the last experiment. Flame arrested by the tin filings and does not enter the balloon.

No. 5. Same as No. 4, but balloon filled with ethoxo gas instead of coal gas and oxygen. Flame passes through the tin filings and destroys the balloon.

No. 6. Same as the last experiment, but granulated pumice used instead of tin filings. Flame arrested and balloon saved.

No. 7. Ditto, ditto, but screened scrapings of slate pencil substituted for pumice. Flame extinguished as before.

No. 8. Ditto, ditto, ethoxo gas being used, but tube filled with a substance known in commerce as "flared glass," screened as described in my last communication. Flame passes through the glass and shatters the balloon.

No. 9. Same as No. 8, but the tube containing the glass removed from the front part of the jet and attached to the tap at the other end. The flame is now extinguished and the balloon saved.

No. 10. Same as No. 9, but with eighteen inches of vulcanised tubing between the tap and the safety tube to increase the volume of the explosive ethoxo gas. Flame extinguished and balloon saved.

The "flared glass" above referred to was sent to me by Messrs. W. H. Oakley and Co.'s assistant. It consists of rounded particles of coloured glass which pass through a sieve containing thirty-six meshes to the inch, but are retained by one of sixty meshes. As it is quite free from dust and not liable to be acted on by the gases it seems likely to be a useful material for the purpose we are now considering. It is not, however, equal to pumice granules nor to scrapings of slate pencil in its power of arresting the ethoxo flame, and it reduces the pressure of the gas to a somewhat greater extent (about twenty-five per cent. for a tube half-an-inch long).

No. 11. Two balloons of the same size, filled respectively with ethoxo gas and oxyhydrogen. The balloons are attached alternately to the tap of the jet without any safety-tube, in order that I may count the number of seconds which elapse before the flame passes. The difference is at once obvious, the ethoxo gas exploding in the balloon whilst still half-full, whereas the oxhydrogen burns at the mouth of the jet until the balloon is comparatively empty and the pressure has nearly ceased.

In considering the results of these and many other experiments I notice, in the first place, that the effect of placing the safety-tube in the *front* part of the jet is not what I anticipated. I expected by so doing to give it an advantage, but it proved to be quite the contrary. The explanation of this discrepancy between theory and practice is not obvious, but I may remark that the tube was placed for the sake of convenience *beneath the mixing chamber;* whereas I suggested in my last communication that the right position for it to occupy theoretically would be *above* the mixing chamber, and between it and the nipple.

If any of your readers should be disposed to repeat these experiments I may mention for their guidance that I prepared the hydrogen gas in the way I usually do for lantern work, namely, by the action of dilute sulphuric acid on iron filings. The gas so obtained is not pure, but it answers very well for the lime light.

To find the proportions for giving the greatest explosive power I turned on the oxygen tap of my biunial lantern until the little cone of imperfect combustion at the base of the blowpipe flame *just began to disappear*, and the flame became solid throughout. Repeated trials with a little more H or a little more O satisfied me that this was the best point to hit, namely, sufficient O to burn the H without any assistance from the external air.

In the case of coal gas and ether, both containing carbon, the penetrating power of the explosive flame is greatest when the dark cone at the tip of the jet is about one-sixteenth of an inch long. And if you wish to drive the flame through the cane you must attend to this point very carefully, since the smallest excess of either coal gas or oxygen will cause the flame to stop when it reaches the cane, although it will still explode in the mixing chamber when you turn off the tap of the jet.

The sum of the whole matter, so far as I have been able to ascertain, is as follows:—That the flame of oxyhydrogen gas is more easily arrested by these safety tubes than that of oxygen and coal gas, and oxygen and coal gas more so than the ethoxo gas.

The best materials which I have tried for stopping the flame are pumice and slate scrapings, and next in order metal filings and "flared glass." Porous wood like cane and small shot are not without effect, but stand lower down in the list.

A safety tube properly made and attached to each tap of the jet may be relied on for stopping any of the above-mentioned explosive flames; and the pressure of the gas is not so far reduced as to make the process unworkable.

In my last communication an error occurred in correcting the proofs. In the thirty-fifth line from the top, instead of "No. 6 same as No. 4," it should be "*No 6 same as No. 5.*" As it now reads the addition of a Chadwick back-pressure valve is said to weaken the safety tube; whereas the experiment merely showed that it did not materially strengthen it. T. FREDERICK HARDWICH.

EXTRACT OF *PSYLLIUM* FOR PROTECTING THE SURFACE OF COLLODIO-CHLORIDE PRINTS.

IN a former communication I have recommended to soak the washed collodio-chloride prints in an ammoniacal solution of bleached lac, which imparts to them a very hard surface like that of albumen prints. As this solution is not easy to prepare, and as it changes through the evaporation of ammonia, I have been induced to find another medium, and I think the best of all I tried is an extract of *Semen psyllii.*

A quantity of this is covered with ten or twelve times its volume of cold water, and, after standing for a day, interrupted by occasional shaking, the liquid is filtered, a small quantity of methylated spirits being added. Those who prefer to mount the prints when dry may add some glycerine. After washing the prints are soaked in this fluid for a few minutes and dried. Even prints made on paper prepared with soluble gelatine may, after this bath, be treated like ordinary albumen prints without the collodion film breaking.

If it be desired to give the prints a coating of varnish I find a solution of one pound of copal in two pounds of linseed oil gives a splendid and most resisting covering, if applied with a pad of cotton or a brush. Prints treated in this way may be considered as permanent—neither light, nor air, nor humidity having the least influence upon them. ED. LIESEGANG, Ph.D.

MISTAKES IN EMULSION WORK.

IT is curious, in looking back on the last few years of experimental work in connection with gelatine emulsion, to see how many conditions have from time to time been laid down as essential to success which have afterwards turned out to be by no means so. I cannot, I am sorry to say, claim that I have not been among the mistaken ones; for I find that at times I have insisted on certain conditions which I now consider to be quite unnecessary, or even believe objectionable.

I would take several of the conditions which it was at one time thought essential to observe when great sensitiveness was required and say a few words on each, giving the results which have been indicated by recent experiments.

It was generally considered, some years ago, that if an emulsion were to be rapid the excess of bromide should not be very great; that no iodide be introduced; that the solution be neutral or but slightly acid; that the amount of gelatine used in emulsification and subsequent boiling be small; and that the amount of gelatine in the finally-finished emulsion be not great in proportion to the amount of bromide of silver in suspension. I do not mean to say that all these conditions were insisted upon by any one experimentalist, but I think they represent pretty fairly the general opinions held about two or three years ago.

To take first the excess of bromide: it is now pretty well recognised that sensitiveness is more rapidly gained with a large excess than with a small one; and now it is the rule to allow a large excess in almost all formulæ which are published. I am by no means certain, however, that we are not going too far in a direction opposite to that towards which we tended some time ago; that is to say, we incline to use now too large an excess of bromide. There is no doubt that by the employment of a very large excess we have a most rapid transition from the red bromide to the blue (by transmitted light); but when we have gone beyond a certain length in the matter of excess the image which is developed on the plate appears to suffer, becoming thin. Recent experiments incline me to think that a good amount of excess to have is about ten per cent.; that is to say, let there be used ten per cent. more bromide of ammonium or potassium than would be required to convert the whole of the silver nitrate to silver bromide. This will give sensitiveness in a fairly short time, and will produce a plate giving good density. I lay down the ten per cent. excess merely as an approximation, because the excess required or permissible may vary with other factors.

With regard to the introduction of iodide in emulsions it appears unnecessary to speak, as the subject has been treated recently by the Editors. I may just say, however, that I can corroborate their statement that a more rapid emulsion can—under certain circumstances, at anyrate—be made when iodide is present than when it is not; in fact, I consider iodide a necessity if we wish a very rapid plate of good quality. As to the amount: I could recommend, if potassium salts be used, three to four per cent. of the quantity of soluble bromide.

I now come to the question of acidity of the solutions, and here I must say that I have got some results which have surprised me very much. Before, however, taking into consideration the acidity of solutions, I would say a few words on the effect of one of the constituents of an emulsion which requires more attention than has been given to it. This is none other than the water which is used to dissolve the chemicals. This little matter has had but small attention, having been once or twice casually mentioned, but, so far as I know, never having received any considerable share of consideration; yet it is the one which ought in reality to have, perhaps, more than any other ingredient of the emulsion.

It may surprise some emulsion experimentalists to hear that, allowing the quantities of all the constituents of emulsions, with the exception of the water used in emulsifying, to remain the same, and varying the water only within the limits found in published formulæ, we may get two emulsions—one of which will require five hours of boiling to produce sensitiveness, whilst the other will require but ten minutes! This is an enormous difference, as will naturally be observed. Still I have found it so. The largest total quantity of water which I remember to have heard recommended for an emulsion in which 400 grains of silver nitrate are used is twenty ounces. The smallest is seven ounces. With the first-mentioned quantity it will usually be found that several hours of boiling are necessary before the blue silver bromide is produced. With the latter quantity only a few minutes is necessary. I must state, however, that I have never been able to cause the silver bromide produced from 400 grains of silver nitrate to suspend itself in seven ounces of water and gelatine. Eight ounces is the least quantity in which I have been able to emulsify 400 grains of silver.

To return to the acid, however: I was astonished to find in recent experiments that, when concentrated solutions are used—when, for example, we dissolve 400 grains of silver nitrate and the corresponding bromide solution each in four ounces of water—we may use a very considerable quantity of acid without much increasing the time necessary to gain sensitiveness. I have recently used as much as twenty minims of strong hydrochloric acid with the quantity of emulsion indicated above, and found, to my surprise, that after five minutes' boiling the colour of the emulsion by transmitted light was nearly blue, and that a fairly-rapid emulsion was the result. After a quarter-of-an-hour's boiling the change of colour was complete, and the emulsion decidedly rapid. At the end of half-an-hour's boiling it was very rapid, and here the experiment stopped; but from the quality of the plates, which would stand very great forcing without showing fog, I have no doubt that boiling might have been continued much longer. The plates were marvellously bright, and gave good, clean images. I consider the use of this large amount of acid mentioned to be most useful.

Another point on which opinion is rapidly changing is with regard to the amount of gelatine present during emulsification and boiling. It was until recently considered that the smaller the quantity of gelatine used at this stage of the process the more rapid would be the emulsion, or, at anyrate, that sensitiveness would be the more rapidly gained. I have always held that the amount of gelatine might be increased considerably beyond the minimum which it is necessary to use to keep the silver salts in suspension without in any way retarding the accession of sensitiveness; but it was not till recentlythat I discovered to how great a length we might go in the direc ion indicated. I think the best plan will be to give at this stage a formula which incorporates the several points that have been, or are to be, mentioned, and which I should have pronounced had I seen it a month ago to be one quite incapable of giving a rapid emulsion:—

A.

Silver nitrate	400 grains.
Water	4 ounces.

B.

Bromide of potassium	296 grains.
Iodide of potassium	20 ,,
Nelson's No. 1 gelatine	200 ,,
Hydrochloric acid	20 minims.
Water	4 ounces.

C.

Heinrich's gelatine	800 grains.

Water to soak this.

Now, it will be seen that in this the amount of gelatine used in emulsification is very great indeed; yet the formula is the very one used when I got the results mentioned in connection with the large quantity of acid used.

It may be asked—Why use so large a quantity of gelatine if less will serve to suspend the bromide of silver? I believe that not only do we get as great sensitiveness with the large quantity as with the small, but that we secure possibly more, whilst we certainly get more density of image. This I believe to be due to the partially-decomposed gelatine which results from the boiling.

I have proved to my own satisfaction that decomposed gelatine has the property of giving dense negatives in the following manner:—An emulsion was prepared by precipitation. A certain quantity of meta-gelatine was prepared by adding ammonia to a gelatine solution, and boiling till all trace of ammonia fumes had disappeared. This meta-gelatine added to the emulsion prepared by precipitation increased sensitiveness a little, and density of image somewhat more. It also brought about green fog; but, possibly, had the meta-gelatine been produced by long boiling instead of by the use of ammonia the result would have been different.

With regard to the point which is last mentioned, namely, the amount of gelatine finally put into the emulsion: it will be seen that in the formulæ given this is unusually large. In spite of this I find that the emulsion is certainly not made any slower by the use of it, nor is there any thinness of image produced, whilst, of course, a larger quantity of emulsion is obtained.

In conclusion: I would ask your readers to give the above very unpromising-looking formula a trial, and report results. I think I can guarantee that the emulsion will stand an hour's boiling without showing any fog. W. K. Burton.

ALTERING THE DENSITY OF GELATINE NEGATIVES.

[A communication to the London and Provincial Photographic Association.]

It may well be imagined that, as the post of lecturer has previously been filled by so many able men, I naturally feel a certain amount of hesitation in attempting to follow in their wake, and I must confess that my native modesty would have prevented me from so doing but for the following reasons, which I must ask you to hold as sufficient excuse for occupying your time this evening.

In the first place: I have always held the theory that each member of a society such as this should endeavour to do something to make its meetings interesting, even though he may not be able to impart much information. We cannot all read papers detailing original and elaborate experiments, nor discourse learnedly and eloquently on scientific subjects; but everyone, amateur or professional, should at least *try* to do more than simply absorb as much as possible from the brains of others without, in return, doing his share in bringing forward matter for profitable discussion.

Another reason is that I thought possibly the example of one of the rank and file might induce others to come forward who, till now, have kept too much in the background. Under these circumstances it was somewhat difficult for me to find a satisfactory excuse when our indefatigable Curator wished to press me into the number of monthly lecturers.

Our subject this evening is *Altering the Density of Gelatine Negatives*. Some there are who say they scarcely ever require to do this; but it may, I think, be taken for granted that, notwithstanding improvement in the quality of plates and better illumination of the dark room than formerly, it is still adviseable frequently to slightly modify the density of the image after fixing, if the best results be desired. What constitutes "proper printing density" I shall not attempt to define. No two photographers taken at random would be certain to agree on that point, and I shall content myself with alluding to the means whereby we may secure the end, without taking upon myself to set up a standard.

Inasmuch, however, as *lowering* rather than *increasing* the opacity is the easier (if colour and permanence are to be taken into account), it is preferable to make sure of sufficient density to start with, and *reduce* if necessary, than to stop development too soon and have to intensify.

Reduction of density may be obtained in several ways; and the following remarks will apply pretty equally to negatives or positives (with, perhaps, the omission of lantern slides), and, excepting the action of acid, to results obtained by pyro. or oxalate development. Negatives may be uniformly too dense, or have the high lights too thick and the half-tones thin; or there may be excess of detail with, at the same time, too great general opacity. The treatment of the negative must depend, therefore, on the existing gradation.

We will consider, first, the cases in which a thin layer of the deposit may be removed from the whole film, without injuriously affecting the gradation. On most pyro.-developed negatives acid will produce a change of colour dependent on the amount of yellowness present, and the strength of acid or time of immersion in it. This may be usefully taken advantage of, where only a slight reduction is required, by employing a weak acid (five per cent. will do), and removing and washing the plate as soon as the action has gone far enough. Owing to the tendency of acid alone to produce frilling, it is customary to dilute it with a strong alum solution instead of water.

The weakening effect of acid not being always sufficient, it is desirable to be able to have recourse to other means. These may be—attacking the image only, or removing a layer from the film itself. Hypochlorite of calcium (chloride of lime), hypochlorites of the other alkalies or of zinc, and ozone bleach have a solvent action on the gelatine, and will remove a thin skin from the negative, carrying with it, of course, the silver contained in that portion of the film so dissolved. I have used this method, both successfully and otherwise, but do not recommend it. It was very well till we knew of a better. Gelatines are not equally acted on, the softer kinds yielding too freely. The harder sorts are more tractable; but if hardened still more by alum the softening of the gelatine is likely to proceed but slowly, and then all at once the film commences to come away rapidly, so that great care is necessary to ensure a uniform and certain result. If a heavy stream of water be allowed to fall upon the plate when it is desired to arrest the action by washing off the bleach, the film sometimes gets carried away more in one part than another; and even in holding the negative up to watch the progress of the operation there is a liability to have the film drip off in little rivulets, giving streaky marks. A fine spray from a rose should be used for washing. Ozone bleach may be diluted with about six or eight parts of water. A saturated solution of chloride of lime should be diluted with twelve parts of water.

The methods of acting on the silver alone are many. The metal itself may be dissolved away by cyanide of potassium, or a portion converted into chloride or bromide and dissolved out by hypo. or cyanide. For this purpose ozone bleach with chrome alum has been recommended and employed, but it possesses no advantages over other chemicals more agreeable to use.

Some metals—such as copper, iron, and gold—form two kinds of chlorides (and bromides), one containing more chloride than the other; and when the one with the larger quantity of haloid (that is, the cupric, ferric, or auric chloride) is brought into contact with silver, it gives up a portion of its chlorine to the silver, being itself converted into cuprous, ferrous, or aurous chloride. According to the extent to which this proceeds the image becomes changed into chloride, and, therefore, soluble when placed in the fixing solution. An alteration in colour is produced without dissolving out the chloride of silver; but this would probably darken if left in the film, so should be removed. It is desirable to wash thoroughly before commencing to reduce, in order to prevent stains.

Chloride of copper or cupric chloride is of the three, perhaps, the best to use. Gold is expensive. Iron is, I fancy, more likely to give a yellow colour to the negative than copper. Five grains of ferric chloride to one ounce of water is a good strength. A few drops of hydrochloric acid in addition has been recommended. It may, if preferred, be mixed with the alum solution. If any pyro. stain exist it should first be removed with acid. The solution can be used until it becomes weak, and then strengthened or thrown away. Ferric oxalate, as you are aware, is also used. Its action is similar to that of the chloride. Captain Abney drew attention some two or three years ago to the fact that its presence in old oxalate developer was a cause of thin images, the metallic silver being attacked as soon as formed.

Cupric chloride is a very nice reducer—easy and clean to use. I have employed it for some time, and find a suitable strength to be—

Copper sulphate	4 grains.
Sodium chloride	6 ,,
Water	1 ounce.

The stock solution may, if preferred, be made more concentrated and diluted for use. If a good quantity be kept in the dilute state it can be used over and over again for some time without getting weak. When it is thought tha the silver has been sufficiently acted on, the negative is washed and flowed over with, or placed in, clean hypo. If not reduced sufficiently, after washing the operation should be repeated.

The cuprous chloride formed is not readily soluble in water, but is easily washed out if the plate be dipped into weak acid and alum after the hypo. has been removed. As the cuprous salt while in the film gives a slight brownish tinge its removal lowers the density a trifle more, and a little allowance should be made for this. With practice there is no difficulty in obtaining any required reduction. Should the solution by any chance be used too strong, or from unequal wetting of the plate with it the negative be more affected in one part than another, the plate should be left in till the image is bleached right through, and then, after treating with acid and washing, be redeveloped, again washed, and the reducing resorted to. If washing between each operation be not pretty thorough, stains will probably make their appearance.

I now call your attention to an exceedingly easy, clean, and practical method to which publicity was given by Mr. E. Howard Farmer in the *Year-Book* for 1884. The reducing agent is ferrid-cyanide of potassium; and, as this can be mixed with hypo. and will remain clear for some time, we have the very decided advantage of requiring only one solution instead of two. The slight uncertainty which always exists where reducing consists of two operations is here removed. I had been experimenting a little in this direction last year, but on the appearance of Mr. Farmer's article I found that someone else had forestalled me.

Mr. J. Spiller's modification of the chloride of copper process, published in the ALMANAC at the same time, was an attempt to do away with the use of hypo. by employing a saturated solution of common salt along with the chloride of copper. In my hands the strength of cupric chloride recommended by him is too great for the operation to be well under control, and the action of the sodium chloride does not seem to keep up with the copper, so that the image gets converted into chloride of silver faster than the sodium chloride will dissolve it out. Possibly an alteration of the proportions might give satisfactory results. The ferridcyanide of potassium I prefer to use rather stronger than suggested by Mr. Farmer, namely, about three grains to one ounce of a five-per-cent solution of hypo. It must be used fresh, and the negative is allowed to remain in this till sufficiently reduced, and then well washed. As there is then a slight yellowish tinge imparted to the film the plate may be dipped in acid and alum after previously washing it. The ease and certainty of this process will commend it to all who try it.

The double oxalate of iron and potassium found in old oxalate developer has been recommended when dissolved in water with hypo. This, it is said, will keep. As it does not appear to possess any advantage over the process just named, and as those who do not use oxalate developer will find it easier to obtain the ferridcyanide (red prussiate of potash) than this double salt, I have not thought it necessary to do more than allude to it.

Cyanide of potassium alone will act on the silver, but not quickly, and I think on the finer details most. I am speaking now of a solution applied to the plate. Mr. A. L. Henderson has told us that it may be better employed by exposing the plate face downwards to the fumes arising from a strong solution. One of the conditions of success is that the film must be thoroughly wet right through, so as to be soft and easily permeated by the fumes, and that the surface of the negative should be wiped free from drops of water; otherwise the reduction will not take place uniformly. Some of Mr. Henderson's experiments do not, when repeated by others, quite tally with his own; but in this case, as the negative I send round shows, if the details are attended to any amount of reduction can be obtained. Strength of solution, about one in six; distance of plate from liquid, perhaps three-eighths to half-an-inch. At the end of fifteen minutes no change observable; in three-quarters of an hour, some reduction; in an hour and a-quarter, a considerable lowering of density had resulted. Still it does not come up to the ferridcyanide of potassium and hypo. method. The time required is too long for anyone to stand by and watch it, and if the dish be placed on one side there is always the possibility of forgetting it till the action has gone just a little too far; whereas Mr. Farmer's process is quick or slow, according to the strength of the solutions, and quite under control. It is, therefore, equally applicable to large or small plates. In using the plain cyanide it is advisable to lift the plate up frequently, as, if the air charged with cyanide fumes long remains stationary, irregular markings might be produced.

Local Reduction of Density.—When the dense part is of a fair size a good way is to flow over first with a weak solution of the chemical employed, and then to pour on and off a stronger solution, letting the liquid impinge on the plate where most reduction is needed. When, however, the too intense portion is of small dimensions, as in the case of a hand or finger, it is better to partially dry the negative, so that the liquid shall not readily spread, and apply with a brush, keeping the outline sharp. A still better way is to paint carefully with a tough varnish round the part to be reduced, and when it has hardened to brush over with the reducing agent. Unfortunately, ordinary spirit varnish has a tendency to split up when wetted with water, so that there is danger of the chemical finding its way through the cracks and producing markings where not wanted. For this reason I think a thin asphalte or turpentine varnish is the most suitable to use. After the plate has been washed and dried the surface should be cleaned by rubbing with spirit or turpentine and varnished in the ordinary way.

Selective Reduction.—Thinning the shadows more than the high lights, or *vice versâ*. The building up of the image in development commences at the surface and proceeds gradually down through the film; the silver forming the detail in the half-tones and shadows, therefore, lies pretty much on the surface. As in most reducing processes an even layer of silver is attacked, it follows that the shadows lose proportionately more than their share, so that there is rarely any occasion to act specially on them. It may happen, however, in the case of a much over-exposed and over-developed negative that it would be improved by a little thinning down, chiefly in the shadows. Such a negative would, perhaps, be best treated by reducing it altogether—which would, of course, leave the shadows barer—and then intensifying what is left of the image.

Reducing the high lights only is much more difficult. The theory is good, but the method of carrying it out requires perfecting. In a leading article in THE BRITISH JOURNAL OF PHOTOGRAPHY for April 20th, 1883, it is suggested to convert the whole of the silver into chloride and then redevelope with ferrous oxalate, using a large amount of restrainer. When all is developed except the highest lights the negative is washed and dipped in hypo. to dissolve the remaining undeveloped chloride. In this manner the detail in the shadows would be preserved. Easy as this looks on paper it is not so easily performed in practice.

At a meeting of this Society sometime last autumn, at which I was not present, I saw by the report that a discussion took place on abrading the film with hard powder rubbed on with the finger or a stump. If any present have tried this method perhaps they will give us the benefit of their experience. Cigar ash appears to me best suited for the purpose. I have tried it on waste negatives, but without sufficient success to warrant me in using it on a negative of any value.

Intensification of Negatives.—On this subject I have less to say than on the preceding one. When it can be seen while developing that the image is showing on the back of the plate before the details are out, a more brilliant print will be obtained if the developer be washed off as soon as sufficient detail appears and intensification resorted to than if it be attempted to get printing density by allowing the plate to soak till it has acquired enough pyro. stain to make it dense. Granted that a negative is to be strengthened, the question arises what shall be used. There are in the market some preparations the composition of which has not been made public. Of these I shall say nothing.

If a very little additional density be needed it will suffice, after fixing, to dip the plate in fresh hypo. solution containing about five or ten per cent. of ferrous sulphate. This is rather of the nature of a stain than a deposit on the silver already forming the image, so does not impart much brilliancy; but it is, nevertheless, useful at times, when the negative is merely thin but not over-exposed. Where more than a slight increase of intensity is required we must resort to other methods, of which we have several to choose from. The principal qualities desired are permanence, a suitable colour for retouching, and ease of application. Unfortunately, these do not always go together. The first is nearly always wanted for any class of work; the second is immaterial for general landscape and architectural purposes, copying, &c.; but for portraiture a good colour is very important.

Silver intensification has always been recommended by the editorial department of one of our photographic journals. The chief condition necessary to success is that all hypo. should be thoroughly removed from the film. It does not, however, follow that all makes of plates are equally amenable to this treatment. Those which have a matt surface take the silver best, and some gelatines are much less liable to stain than others. If the negative be not filled up much in the shadows, and possess proper gradation, silver intensification is certainly to be recommended. It must be borne in mind, though, that since the silver is deposited on the surface there is a tendency to flatten the image, as the half-tones receive nearly as much fresh silver as the high lights. For this reason it is less suitable for over-exposed, flat negatives than some other methods. Bleaching the image with an iron or copper salt and redeveloping has been recommended. I do not find that after clearing with acid to remove the discolouration of the film which is produced there is much increase in opacity.

Negatives intensified with uranium salts are, I believe, found to get denser by keeping. The colour also is objectionable for portraiture. Two processes which give very similar results are Monckhoven's and mercuric chloride, followed after washing by ammonia, the negative being then placed in water containing a few drops of a solution of sulphuretted hydrogen in diluted glycerine. The colour with either of these is a nice brownish black. I have here a series of little negatives, intensified about eighteen months ago by various intensifiers, and so far as I can judge there has been no deterioration in those treated by the two methods just named. These, however, will not always impart sufficient density to very thin, over-exposed negatives. For this there is nothing, I think, so useful as bichloride or iodide of mercury, followed, after a thorough washing, by Schlippe's salt. I do not recommend this for portraiture where it can be avoided, because of the reddish-yellow colour which renders the retouching of such negatives a matter of difficulty. So far as preserving gradation and being under control is concerned it answers every purpose. I was somewhat surprised to see some little time back, in the "Answers to Correspondents" given in a photographic journal, the statement that this intensifier was only suitable for line work on account of the great density produced. Since the density is easily regulated with a little care and practice, it seems to me that for exceedingly-thin portrait negatives (which, of course, are only obtained now and again through accident) and for general outdoor work (on which retouching is not generally required), more especially for large plates on which it is somewhat difficult to use silver, mercury and Schlippe's salt form a serviceable permanent intensifier.

WILLIAM COLES.

THE OXYHYDROGEN EXPLOSION AT DRURY-LANE.

MOST of the readers of this Journal will have read in the daily or weekly newspapers of the explosion which occurred at Drury-lane Theatre, on Wednesday, the 4th inst.; but as no technical particulars were given, I thought I would attend the inquest on the body of the poor man who succumbed to the injuries he received, to ascertain, if possible, the cause of the explosion, and get any information that might be of value to the lanternists and photographers who employ the lime light.

By the courtesy of the authorities I was enabled to view the scene of the explosion and the materials employed. The room in which the two lime-light men were working was underneath the stage, and had a gas bracket with a wire guard over it placed about four feet from the ground on one side, and a large supply pipe coming down the end wall of the room to the bottom, where there was a large outlet and T connection. I soon found that the accident had not happened while working the lime light—as one would naturally suppose from reading the accounts published—but while preparations were being made for the performance.

The plan adopted at Drury-lane Theatre appears to be that the gas required to be used for the lime light has to be taken into the theatre before the performance, and any left is supposed to be taken out afterwards. There were remnants of two bags on the floor—one (the oxygen) split into shreds, and the other (the hydrogen) rent and injured, but retaining its wedge-shaped form. The oxygen gas bag must have been by some means partly filled with hydrogen as well as oxygen, and one of the attendants must have applied a light for some purpose to the nozzle, or by pressing on the bag while it was connected with the large supply pipe and then withdrawing the pressure drew down the flame to the bag and so ignited what had become, by mixing, an explosive gas. Or it may be that the light caught some part of the material of the bag, set it on fire, the oxygen feeding the flame and becoming so rarefied that it soon burst. From the fact that the poor fellow that died having been very much injured in the lower part of the body it seems likely that he was standing over or behind the bag with his legs apart, probably giving some attention to the bag when the explosion occurred.

I noticed that the bags were about the same colour; that the stopcocks were the same size and colour; and that although there was an "H" on the hydrogen bag, which was the larger one, it was only temporarily marked—not in a bold and unmistakable manner. This being so, the question arises—What precautions can lime-light operators take so as to secure the minimum risk? I would suggest—

1st. That each bag should be marked with an "H" and an "O" respectively, so that it could be seen *at once* in a very faint light—a good block letter of a large size on both sides of the bag; and it would not be amiss, as an additional precaution, if on the wedge as well. If the bags be black or brown, the letters should be in white paint; and if a light-coloured or chequered bag, then black paint.

2nd. That the tap or stopcock of the hydrogen bag should be of a different pattern and size to that of the oxygen bag, so that a connection could not possibly be made unwittingly from the hydrogen or house gas supply to the oxygen receptacle.

3rd. That the colours of the taps and fittings of the two gases should be different—all the hydrogen being bronzed and the oxygen lacquered bright, so as to be distinguished at a glance.

4th. That in *no* case whatsoever should a light ever be applied to the tap of a gas bag, or should any connection be made to a pipe or service on which a jet may be *alight* if there be any chance whatever of the gas bag, while filling, being disturbed.

5th. That if any doubt exist as to the nature of the gas in the gas bag or holder, it should, before applying a light to any attachment to the outlet pipe, be passed through a water interceptor, so made that only a small quantity of gas could collect above the water, and this, in the case of ignition if it exploded, would blow out a cork or india-rubber bung lightly fitted in an aperture at the top.

Nearly all the serious explosions I know of or can learn anything about have been the result of accidental mixing of gas in the bags or holders, or the choking up of the pipes while making oxygen gas. With care this should not occur; but, as apparently inexplicable things do sometimes happen, I would impress on all lime-light operators the necessity of having safety-valves or vents to *each* part of the apparatus where an explosion could occur, and from its construction, by blowing about any portion, do serious damage. For instance:—The retort for oxygen making should have inserted in the top a tube three or four inches long, lightly covered by an india-rubber cap, cork, or spring valve, so that when the pressure of gas became greater than would naturally pass through the outlet the cork would rise and form a vent. The purifier or wash-bottle should also have a bung inserted to form a vent; in fact, it is better to use more than one purifier, so that the gas may be thoroughly purified and dried. I would therefore suggest that two should be of the ordinary form, having an inlet pipe going to nearly the bottom, and an outlet pipe inserted at the top, and the third a water interceptor.

One of the ordinary purifiers I would have empty when making oxygen, and place it next the bag for filling; the next should have water in; and the third, that nearest the retort, lime dust and water or caustic soda. The result of this would be that the chlorine in the oxygen gas would be stopped by the purifier next the retort, the gas would be cooled in the second, and dried in the one next the bag. There is no doubt that having an empty purifier next the bag saves the material of the gas bag from wear very considerably, by stopping the particles of moisture which tend to rot it if deposited inside; and any one who uses this plan can testify that often there is a measureable quantity of water in the purifier that was empty before commencing operations.

I fear there are a great number of oxygen retorts still in use that have no safety outlets if the delivery tube get choked, and I would advise all who have such to get them altered at once. It is a matter of duty to do so. I recently saw an apparatus, issued by the Government for some special work, and this had no safety-valve; and when we remember that one fatal accident occurred some years ago through the retort toppling on one side and the delivery tube getting choked, it cannot be urged too strongly by all interested in the lime light—in fact, insisted on—that the apparatus employed shall be the safest possible. No steam-engine is without its safety-valves; so no oxyhydrogen apparatus must be without means to render mishaps comparatively harmless.

To sum up: I am of opinion that no lanternist or photographer need hesitate to use the lime light if he will, first of all, master the principles on which the light is worked and the nature of the gases employed. But what is to be deprecated is the haphazard employment of apparatus new to the operator without having received proper instruction in the use of the same. There is something to learn in everything, and it is not because an explosion of ordinary gas occurs in a house, through a tap having been left turned on or through some other accidental occurrence, that the use of gas for illumination is to be prohibited. So with regard to the lime light: it must not be admitted for one moment that prohibition can be tolerated. The great thing is to exercise care in all details, and remember that under no circumstances are the oxygen and hydrogen gases to be allowed to mix until the moment they are emerging from the jet to produce the light.

G. R. BAKER.

WE have received the following report of the adjourned inquest from a correspondent who was present:—

LONDON not being troubled enough by explosions caused by "dynamitards"—whose proper appellation is certainly "fools"—must occasionally have a further addition in the way of lime-light bursts caused by gross negligence and the employment of incompetent men. Such an one occurred on the afternoon of the 4th instant at Drury-lane Theatre, resulting in the death of one man within twelve hours, and such injuries to the other that from his appearance the meeting of the "mates" in the "great beyond" will not be long delayed.

The coroner's inquest commenced on Monday, the 9th instant, at King's College Hospital, where both the injured men—Harris and Creed—were conveyed after the "incident," as a theatrical contemporary called it, but was adjourned, after the body of poor Harris had been identified by his brother, for the dual purpose of getting Creed's evidence and communicating with the Home Secretary, the Coroner (Mr. St. John Wontner) stating that the affair came under the Explosives' Act. James Harris's trade was given as that of a "boot finisher."

After the adjournment the jury proceeded to the theatre to view the *debris*. After descending a flight of stairs, and being guided along a narrow and tortuous passage, a cellar fourteen feet by ten feet was reached, where the "incident" occurred. One wall slightly bent; the plaster from the ceiling transferred to the floor; the laths hanging in grotesque fashion, resembling an uncombed head of hair; fragments of what had been a gas bag, with another one split in twain up the gusset, lying in the centre of the room; and the door off its hinges—all these attested the fact of the two gases having been in loving company in one receptacle.

On Monday last, the 16th instant, the inquest was resumed. The Coroner read a letter from the Home Secretary, who stated that as the matter was not within the scope of the Explosives' Act of 1875 it was unnecessary for any one to attend from his office.

James Creed, who is still suffering severely from his injuries, was the first witness. He was a painter by trade, but had also been working the lime light for eighteen or nineteen years. Three hydrogen bags were employed; but on this particular afternoon he only saw two, and remarked to Harris—"Jim, there is something wrong; we must be careful and see what's the matter, as there were three here last night." Thereupon they both together tried one bag, which proved to be oxygen. He then saw the gas drawn to the other, cried—"Look out, Jim!" and remembered nothing for two or three minutes, when he cried for help and was rescued by the fireman of the theatre. Replying to several questions, it seems the *modus operandi* was to have five bags—two for oxygen and three for hydrogen; that after the lights had been used in the flies the bags were conveyed to the cellar, where the oxygen was transferred to one bag, the other being replaced by a full one sent from Mr. Kerr's factory daily. The hydrogen bags were replenished in the dungeon bearing the *soubriquet* of the "lime-light room," doubtless on account of its darkness. Harris being on the prompt side, got into the cellar first, and commenced transferring. He was followed by Creed, who, of course, could not account for the explosion. It might have been during the transferring process, or a bag might have been sent mixed; but he could not say how it went off. He had never had an accident before. He received 1s. 6d. for each performance. All the bags were one colour, not marked, and had taps alike, though the rule was that they should be different colours and marked, as well, "O" and "H."

Thomas Donovan, a private fireman at the theatre, heard the explosion and saw the scenery in the "scene dock" jerked from side to side. He went below and rescued the men from their perilous position. The next "room" was found damaged.

Mr. James Matthews, Assoc. M. Inst., C.E., the gentleman employed by the renters of Drury-lane Theatre as gas engineer, happened to be in the house when the explosion occurred, and, guessing its cause, hurried downstairs and turned off some twenty-five burners which had been extinguished in the passages. As he heard the sound of escaping gas in the room, he felt down the wall and discovered an aperture connected with a T-piece provided with a cock for the express purpose of filling the bags. Not finding a plug at hand the right size, he inserted a tap from one of the bags, of which he noticed five, two being dismembered, one marked "H," and the other three filled—one with oxygen, two with hydrogen. He had them placed in Vinegar-yard. Replying to a juror, he stated that the men who worked the light were recruited from all trades on account of cheapness; that they soon acquired enough skill to work it; and that there was absolutely no danger.

Mr. Walter Kerr, whose apparatus was used, supplied the oxygen from his factory at Adelphi Arches, Strand. He described how the gas was furnished, the hydrogen being taken from the main. When asked why he did not use bags of different colours he stated that the black ones did not last. [A desultory wrangle here ensued, it being suggested that they were marked, as sheep are, with red chalk.] The bags were new. No competent man would try gas by putting a light to the bag, but would fill an india-rubber tube, put one end in the mouth and blow it through a gas flame! He considered the men he employed were competent, and adduced the fact of Creed's experience of nearly twenty years.

After the doctor had stated the cause of death, Mr. Baker (representing Mr. J. H. Steward, the lantern specialist), kindly offered by the aid of a pair of model bags to explain the effect of suction, &c., but the jury considered the evidence sufficient and retired to consider their verdict, with which they returned in a few minutes, and which was that death was caused from an explosion of gas, the origin of which the evidence was not sufficient to prove. A rider stated that the lime light was worked at Drury-lane Theatre by incompetent men, and in an unfit place under the stage.

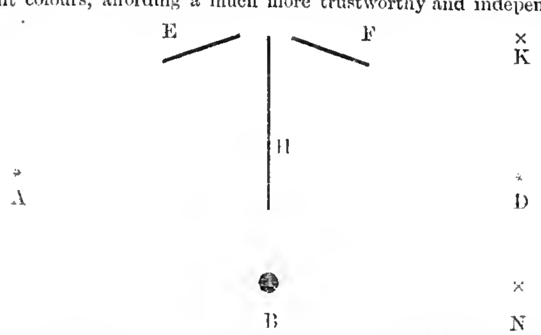
From the contradictory evidence it will be seen that no one knew how the accident occurred, further than that it was clear enough that a bag of mixed gas had a light applied to it. How much longer theatrical managers are going to have such things as bags, and "boot finishers" and "painters" to use the light, is hard to tell. These folks show the crassest ignorance of science, and when as occurred within my knowledge, "them 'ere lime lights"—as the artist in charge called the apparatus, consisting of lens, box, two bags, pressure-boards, and six fifty-six-pound weights—fell on the stage just as an actor (fortunately for him) made his exit, it seems time that such antique machinery should be consigned to oblivion in some "lime-light room" where they never more would cause trouble by their explosive presence.

SIRIUS.

THE ROYAL INSTITUTION.

A PHOTOMETER FOR COMPARING COLOURED LIGHTS.

ON Thursday, the 5th inst., Professor Dewar closed his series of lectures at the Royal Institution on *Flame and Oxidation*. In the course of the last two lectures the chief matter of interest to photographers dealt with by him was a photometer for measuring the relative intensities of lights of different colours, affording a much more trustworthy and independently



verifiable method of comparing them than that at present in use, during experiments in developing-room illumination, by ascertaining the distance from a screen at which small print can be read by an individual. Professor Dewar said that it was impossible to compare the relative intensities of lights of different colours, except by means of a "shadow" photometer, one of which he had fitted up behind the lecture table. It consisted of a fixed coloured light A, and a movable one D. At H is a screen, consisting of a piece of cardboard with a star cut out of its centre; over the cardboard, on each side, is then pasted a very thin piece of translucent paper. The eyes of the observer are at B, and he sees both sides of the screen H by reflection from the two mirrors E, F. By shifting the light D until the lights are so balanced that the star can no longer be seen on either side of the screen H, the relative intensities of the two coloured lights are ascertained by their relative distances from the screen. The mechanism was of such a nature that he could also shift the light D in the direction K or N, so that when desirable he could measure its intensity when it fell upon the screen H at other than a right angle.

The lecturer said that in flame the combustion is not perfect except near its apex; near its root a certain amount of dissociation is going on, and the heat of the flame is greater where the combustion is less perfect. Combustion often takes place more quickly with hydrogen than with carbon; for instance, an explosion travels more rapidly through a long pipe filled with hydrogen and oxygen than through a similar tube filled with carbonic oxide and hydrogen. Many varying conditions come into play in obtaining the maximum possible light from coal gas. One way is to pass the gas over napthaline crystals placed in a bulb near enough to the burner to be slightly warmed by it; this much increases the illuminating power and promotes economy. He spoke favourably of the fishtail burner for common gas.

Professor Dewar also gave the results of some experiments he had been trying as to the influence of the London combustion of gas and coal on the local atmosphere. A sheet cleaned with carbonate of soda, then well washed in changes of clean water, and when dry painted with paraffine, was stretched over a part of the roof of the Royal Institution to catch the rain-water of showers, and the water thus collected ran into a bottle through a hole in the middle of the sheet. The rain, of course, washed the air through a great height, and brought down its soluble contents. The first shower brought down more impurities than succeeding showers; these impurities consisted of sulphurous acid, sulphuric acid, ammonia, and albumenoid ammonia. The slightest trace of sulphurous acid in the air has great influence in promoting dense fog; aqueous vapour by itself is not nearly so mischievous in this direction. He proved this by experiments showing the condensation of pure aqueous vapour in a bell jar, and also its condensation when mixed with a trace of sulphurous acid. He then exhibited a method of cooling flame, so as to vary the character of its combustion, and to permit different parts of it to be examined by the spectroscope. The plan consisted of causing a thin sheet of water to flow down one side of a glass plate, the flame being then laid against the sheet of water, and examined from the other side of the glass. The flame of cyanogen has a purple colour, and a much higher temperature than any ordinary flame; it also gives a most magnificent and remarkable spectrum, due perhaps to a complicated molecule of carbon. This flame contains no hydrogen, so is in reality a flame of pure carbon. The chemical reactions taking place within it differ from those in any other carbon flame.

THE PLATINUM PHOTOMETER.

Professor Dewar stated that at present all statements of illuminating power are in England referred to a standard candle—a crude method, because the quality of the candle cannot be guaranteed; it also does not give a steady light, and is affected by currents of air. The French early adopted a flame from the combustion of oil, and their standard—the Carcel lamp—is undoubtedly steadier than ours. At the Electrical Congress it was proposed to adopt some better standard, and the light from a measured surface of platinum at its melting-point was suggested, the surface of platinum being so unalterable. The present best standard of white light is, therefore, that of platinum at its point of solidification. An error is abroad in the supposition that this standard is supposed to be in direct use by everyone who makes photometrical experiments. It is not so. The platinum standard is for the purpose of verifying the accuracy of the Carcel lamps employed; it was never supposed that every experimentalist would carry fusing platinum about with him. He then fused a piece of platinum, and said that in previous experiments he had found the following to be the light radiation of platinum:—

Temperature. Degrees Centigrade.	Luminous Intensity.	
	Red rays.	Green Rays.
954	1·00	1·00
1,045	3·27	3·64
1,500	154·00	219·00
1,775	507·00	809·00

$I = m\,T^3\,(1 + ea^{-T})$ when T = absolute temp. Luminous intensity above 500° increases as the T^6 for red rays and as T^7 for green rays. As the proportions of the coloured rays to each other vary at different temperatures, mean white light is taken as a photometric standard, and not individual rays.

The lecturer then proved by experiments that by diminishing the pressure of the air round a candle perfect combustion will still go on steadily and without smoke, but the intensity of the light is diminished. Probably, however, a new kind of combustion is set up. In the course of some experiments with acetylene, he passed the latter into a solution of oxide of silver in ammonia; a white precipitate of acetylide of silver was the result. He did not say whether it had any photographic properties. He stated that the oxyhydrogen flame does not give a continuous spectrum, especially in the invisible part, and the bands are chiefly due to water. When gases contain ammonia, and the temperature of the flame is not very high, prussic acid can usually be drawn from the centre of the flame. He closed the lecture by describing the principles of combustion in gas engines, and by giving a description of the new source of supply of petroleum from Southern Russia, near the Caspian Sea. It was shown to give a slightly better light than American petroleum.

DR. GILL ON PHOTOGRAPHY AND ASTRONOMY.

[Extract from a Lecture delivered at the Royal Institution.]

I wish briefly to allude to another engine of research in sidereal astronomy which quite recently has received an enormous development, and whose application appears to offer a rich harvest of results. I refer to the application of photography to astronomical observation.

Your respected member, Mr. De la Rue, is the father of this method. Time does does not permit me to dwell on his early endeavours and his successful results, but they are well known to you all. He opened up the field, and he cleared the way for his successors.

The recent strides in the chemistry of photography and the production of dry plates of extreme sensibility have permitted the application of the method to objects that formerly could not be photographed. Here, on the screen, are the spectra of stars photographed directly from the stars by Dr. Huggins, the lines which tell of the chemical constitution and temperature of the star's atmosphere being sharply defined.

Here are photographs of the great comet of 1882, which, with the co-operation of Mr. Allis, of Mowbray, I obtained at the Cape, by attaching his ordinary camera to an equatorially-mounted telescope, and with its aid following the comet exactly for more than two hours. Each one of the thousands of points of light that you see is the picture of a fixed star. The photograph suggests the desirability of producing star maps by direct photography from the sky.

Here on the screen is a photograph of the great nebula of Orion, or rather a series of photographs of it, made by Mr. Common, of Ealing. You will note the gradual development of detail by increase of exposure, and the wonderful amount of detail at last arrived at. Here are photographs from drawings of the same, and you will note the discrepancies between them; and here is a photograph of a star cluster, also by Dr. Common.

No hand of man has tampered with these pictures. They have a value on this account which gives them a distinct and separate claim to confidence above any work in which the hand of fallible man has had a part.

The standpoint of science is so different from that of art. A picture which is a mere copy of nature, in which we do not recognise somewhat of the soul of the artist, is nothing in an artistic point of view; but in a scientific point of view the more absolutely that the individuality of the artist is suppressed, and the more absolutely a rigid representation of nature is obtained, the better.

Here is a volume compiled by one of the most energetic and able of American astronomers—Professor Holden. It contains faithful reproductions of all the available drawings that have been made by astronomers of this wonderful nebula of Orion from the year 1656 to recent times.

If now we were to suppose one hundred years to elapse, and no further observation of the nebula of Orion to be made in the interval; if in some extraordinary way all previous observations were lost, but that astronomers were offered the choice of recovering this photograph of Mr. Common's, or of losing it and preserving all the previous observations of the nebula recorded in Professor Holden's book, how would the choice lie? I venture to say the decision would be—Give us Mr. Common's photograph.

Is it not, therefore, our duty to commence a systematic photographic record of the present aspect of the heavens? Will not coming generations expect this of us? Does not photography offer the only means by which, so far as we know, man will be able to trace out and follow some of the more slowly-developing phenomena of sidereal astronomy?

Huggins has shown how the stars may be made to trace in significant cipher of their spectra the secrets of their constitution and the story of their history. Common has shown us how the nebulæ and clusters may be separately photographed, and it is not difficult to see how that process may be applied, not only to special objects, but piece by piece to the whole sky, till we possess a photographic library of each square half-degree of the heavens. But such a work can only be accomplished by consummate instruments, and with a persistent systematic continuity which the unaided amateur is unable to procure and to employ. It is a work that must be taken up and dealt with on a national scale, on lines which Huggins and Common have so well indicated, and which has already been put in a practical form by a proposal of Norman Lockyer's at a recent meeting of the Royal Astronomical Society.

I would that I had the power to urge with due force our duty as a nation in this matter, but my powers are inadequate to the task.

I employ rather the words of Sir John Herschel, because no words of mine can equal those of him who was the prose poet of our science, whose glowing language was always as just as it was beautiful, and whose judgment in such matters has never been excelled. They were spoken in the early days of exact sidereal astronomy, when the strongholds of space were but beginning to yield the secret of their dimensions to the untiring labour and skill of Bessel, of Struve, and of Henderson. Think what they would have been *now* when they might have told how Huggins' spectroscope had determined the kinship of the stars with our sun, how it had so far solved the mysteries of the constitution of the nebulæ, and pointed out the means of determining the absolute velocity of the celestial motions in the line of sight. Think what Herschel would have said of those photographs by Common that we have seen tonight of that nebula that Herschel himself so laboriously studied, and whose mysterious convolutions he had in vain endeavoured adequately to portray; and think of the lessons of opportunity and of duty that he would have drawn from such discoveries, as you listen to his words spoken forty-two years ago:—"Such results are among the fairest flowers of civilisation. They justify the vast expenditure of time and talent which have led up to them; they justify the language which men of science hold, or ought to hold, when they appeal to the Governments of their respective countries for the liberal devotion of the national means in furtherance of the great objects they propose to accomplish. They enable them not only to hold out but to redeem their promises, when they profess themselves productive labourers in a higher and richer field than that of mere material and physical advantages. It is then, when they become (if I may venture on such a figure without irreverence) the messengers from heaven to earth of such stupendous announcements as must strike every one who hears them with almost awful admiration, that they may claim to be listened to when they repeat in every variety of urgent instance that these are not the last of such announcements which they shall have to communicate; that there are yet behind, to search out and to declare, not only secrets which shall increase the wealth or power of man, but TRUTHS which shall ennoble the age and country in which they are divulged, and, by dilating the intellect, react on the moral character of mankind. Such truths are things quite as worthy of struggles and sacrifices as many of the objects for which nations contend, and exhaust their physical and moral energies and resources. They are gems of real and durable glory in the diadems of princes, and conquests which, while they leave no tears behind them, continue for ever unalienable."

David Gill, LL.D., F.R.S.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 8,771.—"Manufacture and Subsequent Treatment of Sensitive Paper for Copying Drawings, Documents Written on One Side, or the like, by Photography." H. J. Shawcross, Lord-street, Liverpool.—*Dated June* 10, 1884.

No. 8,852.—"Uncapping and Capping Lenses." F. W. Branson, Leeds.—*Dated June* 11, 1884.

No. 9,026.—"Producing from Photographic Negatives Blocks or Plates Suitable for Typographic Printing." H. Gardner; communicated by G. Sutherland, journalist, Adelaide, S. Australia.—*Dated June* 16, 1884.

Obtaining Incised or Raised Designs on the Flat or other Surfaces of Steel, &c.

Provisional Specification of Joseph Brown.

In carrying out my invention the improved process is as follows:—

I take a hand drawing, print, or engraving, from which I obtain an engraved plate in one or more sizes by any of the well-known or ordinary methods either by photography, lithography, or copper-plate. From this plate or printing surface I obtain an impression in a bituminous asphaltum, or resinous varnish or material sufficiently strong to be acid-resisting. I then take this print in bituminous or other varnish and transfer it, by slight pressure, on to the surface on which I intend the drawing to be reproduced; the paper being removed leaves me the impression in the bituminous ink or varnish perfectly intact on the plate. I then proceed to protect those parts not forming the design with a wax or other protective varnish, and the print thus transferred to the plate is then gently sprinkled with bituminous powder, should the case require it.

The plate or metal surface in its thin condition is submitted to the action of acids, or an electric battery, or any well-known mordant, until such parts unprotected by the bituminous varnish are acted upon until the required depth is obtained.

This process particularly applies to the production of plates for pottery printing purposes, calico or other textile printing, the production of *cloisonné* of mosaic work in enamels, for the preparation of dyes, for metal and paper printing and stamping, for leather stamping, and for obtaining designs on any other metal above referred to.

Also for obtaining designs on cylindrical rollers either for repeated patterns or otherwise, as well as for producing raised type printing blocks.

In places where the pattern repeats itself I build up as it were or repeat it by multiplication to any extent required.

Improvements in the Production of Surfaces for Printing, &c.

By Joseph Julius Sachs.

My invention has for one of its objects to produce reproductions from photographs, drawings, paintings, or the like, in which reproductions are obtained of the half-tones, full-tones, and lights and shades, so as to give a faithful representation of the original. In order to effect this it is necessary to print from the original, or a transparent reproduction of the same, upon a sensitive ground (such as one of chrome gelatine) with the interposition of a transparent medium, upon which is made a number of fine dots or a grain. This grained or dotted medium it has been proposed to obtain by means of prints from surfaces which have been lined or "cross hatched" by hand and in any other ways, but hitherto it has been impossible to obtain satisfactory results by these means. According to my invention I obtain a dotted or transparent medium as follows:—

I take a metal roller, or other surface of metal or hard material, and I submit it to the action of the impact of hard particles, such as is obtained by the projection of sand propelled by a blast against the said surface. I thus obtain a grained surface of a degree of fineness in accordance with the fineness of the hard particles employed. I then roll over the surface thus obtained, or cover it with ink or an opaque substance, and I take an impression therefrom upon a transparent medium, such, for example, as upon paper or the like prepared as described in the specification of my Letters Patent, No. 3,948, dated 14th August, 1883. I take the transparent medium thus covered with an opaque grain, and I cover it over or place it upon the photograph, drawing, painting, or original to be copied, and then place these together over a sensitised layer such as chrome gelatine, which will become hardened on exposure to light; and I thus obtain by the light passing through the grained surface and the photograph, drawing, painting, or the like, a reproduction of the same upon the sensitive layer which, when it is upon or has been transferred to a roller or other surface and this is treated and etched according to any suitable process (such, for example, as is explained in the specification of my prior Patent, No. 266, dated 21st January, 1881), will give a printing or embossing surface from which impressions can be taken resembling the original. For the purpose of the transfer to the roller or other surface the sensitive layer may, before exposure, be covered with a film of asphaltum or other suitable resist. The grained print or reproduction from the surface treated by the sand blast may be obtained by direct printing upon a transparent medium or by any suitable direct or indirect process of transfer, or it be may printed directly upon the photograph, drawing, painting, or the like without the intervention of a special transparent medium.

In order to give a colour-holding surface to the design eventually produced upon the roller or other surface, I may treat the same (after it has been etched in the etching bath) with the sand blast so as to give a roughened surface to the sunk parts, the raised parts being protected by the original or a special resist or covering.

A further object of my invention is to obtain ornamental effects upon metal surfaces to resemble inlaid work.

According to this part of my invention I take a metal surface and I roughen it by submission to the sand blast or the impact of hard particles, and I then cover it with a sensitive layer which I expose to the action of light beneath the negative or design to be reproduced, whereby the parts exposed to the action of light are hardened. I then roll over or cover the sensitive film thus treated with a resist or ink which adheres to the hardened parts of the sensitive layer, but not to the unhardened parts, which latter may be then removed by washing or in any suitable way leaving the metal at these parts exposed. A metal preferably of another colour or kind may then be deposited by electro-deposition upon the exposed parts, and then on removing the resist and hardened gelatine from the other parts the metal surface will have the appearance of inlaid work. Instead of the process of electro-deposition, I may bite into or through the metal at the exposed parts, whereby I obtain perforated ornamental work resembling lace patterns or other designs which give very beautiful effects when used for decorative purposes. In the process wherein electro-deposition is used the metal at the exposed parts may, before undergoing the process of electro-deposition, be again submitted to the sand blast to give different grains for the design and the ground.

Having now described and particularly ascertained the nature of my said invention, and the manner in which the same is or may be used or carried into effect, I would observe, in conclusion, that what I consider to be novel and original, and, therefore, claim as the invention secured to me by the hereinbefore in part recited Letters Patent, is:—

1st. In the production of rollers or surfaces for printing or embossing purposes, obtaining by means of the sand blast or the impact of hard particles a surface from which a dotted or grained medium is produced, which is placed together with a photograph, drawing, painting, or the like upon a sensitive layer or material which is upon or is afterwards transferred to the roller or surface to be etched, and afterwards treating and etching the said roller or surface, all substantially as and for the purpose hereinbefore described.

2nd. In the production of rollers or surfaces for printing purposes obtaining a colour-holding surface by submitting the said rollers or surfaces to the action of the sand blast or the impact of hard particles, after the design has been etched or produced on the said rollers or surfaces, and whilst the parts which are not to hold colour are protected by a material or substance capable of resisting the action of the said sand blast or impact, substantially as hereinbefore described.

3rd. Obtaining ornamental work by first roughening or graining a metallic surface by the sand blast or the impact of hard particles, then covering it with a sensitive layer and exposing it to the action of light beneath the negative or design to be reproduced, then rolling over or covering the same with a resist or ink, and then removing the soluble parts of the sensitive layer and afterwards submitting the exposed parts to a process of electro-deposition; or of etching or biting through, or, as an alternative, submitting the said exposed parts again to the action of the sand blast or the impact of hard particles, and afterwards to a process of electro-deposition, all substantially as hereinbefore described.

Meetings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society, held on the 12th instaut, the chair was occupied by Mr. A. Cowan.

Mr. A. L. Henderson produced two negatives upon plates which had been exposed to the light and initialed by some of the members at the previous meeting. The effect of the previous exposure had been removed by an immersion in a ten-per-cent. solution of bromide of potassium acidulated with nitric acid. After this treatment they had been washed for about an hour, and dried previous to receiving the second exposure. The sensitiveness was very much reduced, necessitating an exposure of about twenty times that originally required by the same plate.

Mr. W. K. Burton inquired whether Mr. Henderson attributed the action that had taken place to the bromide or to the acid.

Mr. Henderson replied to both.

Mr. J. Barker thought the action was caused by free bromine.

Mr. Burton said that free bromine would eliminate an undeveloped image and even a developed one, but for the latter purpose the solution must be so strong that the whole film might be destroyed.

The Chairman then called upon Mr. W. Coles to deliver his lecturette on *Altering the Density of Gelatine Negatives.* [See page 391.] Mr. Coles illustrated his remarks by demonstrating most of the methods to which he had referred. At the conclusion of the lecture.

Mr. Henderson said that the clearing effect of solutions of citric acid and alum or hydrochloric acid and alum went off if the plate were long washed afterwards. As to reducing the density of negatives: he had saved many by the use of ozone bleach; but since he had found the reducing effect of the vapour from cyanide he preferred, on the whole, that method. A wash of ozone bleach was useful as an application to a negative before intensifying. An objection to the use of the bleach was that with some gelatines it would cause frilling.

The Chairman said that almost all gelatines would stand ozone bleach. He had successfully treated some which were so intense that they would not print in a week before reducing.

Mr. W. Cobb was rather surprised to hear Mr. Henderson say that ozone bleach caused frilling. If the plate were dried before its application there was no danger on that score.

The Chairman's experience confirmed that of the last speaker.

Mr. Burton observed that some gelatines were so hard that they might be immersed in hydrochloric acid (British Pharmacopeia strength) without dissolving.

Mr. A. Mackie said there was a method of treatment which gave some density, but which also allowed of density being reduced if followed by alum and acid. He referred to the method with sulphate of iron.

Mr. W. H. Ashman inquired whether the lecturer had tried reducing intensity by cutting down the surface of the film with an abrading powder. He had treated many in that manner, using either powdered resin or cuttle-fish bone.

Mr. W. E. Debenham said that, in introducing ozone bleach for photographic purposes, he had been influenced by several considerations to select that rather than the hypochlorite of lime solution referred to by the lecturer. Commercial chloride of lime is a compound of variable composition. In any case a saturated solution made from it would probably be saturated with caustic lime, and some carbonate might be deposited in the film. One of the purposes for which it had been brought forward was to decompose and remove the last traces of hypo. from the negative preparatory to silver intensification, when it was intended to use that method.

Mr. Coles said it was true that ozone bleach was a more definite solution than that formed from chloride of lime. The amount of lime deposited in the film from the latter solution was so small that he did not think it was important.

The Chairman objected strongly to any method which would deposit sulphur in the film, such as the employment of an alum bath before the hypo. had been effectually removed.

Owing to the lateness of the hour at which the lecture had terminated it was arranged that the discussion that evening should be confined to the question of reducing density only, and the one upon increasing intensity should be deferred until next meeting.

In reply to a question, Mr. A. L. Henderson said that he intended leaving for New York on the 11th of next month, and while in that city his address would be Grand Central Hotel.

THE POSTAL PHOTOGRAPHIC SOCIETY.

The annual general meeting of this Society was held on Monday last, the 16th instant, at 3, Plowden-buildings, Temple.

Dr. Horace Day having been voted into the chair, and the minutes of the previous meeting read and confirmed, the Hon. Treasurer reported as to the progress and position of the Society, and handed in the following balance sheet, which was approved:—

Balance Sheet of the Postal Photographic Society for the year ending June 18, 1884.

Received.	£	s.	d.	Expended.	£	s.	d.
Entrance fees—46 at 2/6........	5	15	0	Petty cash, stamps, stationery, &c.	10	5	1½
Annual subscriptions—75 at 5/-	18	15	0	Printing, circulars, notices, &c.	1	18	4½
Half-yearly do.—16 at 2/6......	2	0	0	Albums, note books, &c.	4	2	11
One honorary do..............	0	10	0	Prizes...........................	4	19	0
Prize Fund—Donations........	3	1	0	Pall Mall Exhibition	3	0	0
Do. Entrance fees....	6	9	6	Late Sec.'s clerk, and boxes, &c.	2	2	6
Sundry receipts	0	5	0				
	36	15	6		26	7	11
Balance from last year	5	19	2½	Balance—			
				In Bank........ £15 0 0			
				Cash in hand 1 6 9½	16	6	9½
	£42	14	8½		£42	14	8½

Examined with books and vouchers and found correct,
Walter Withall, *Auditor.*

The balance of £16 is forestalled for prizes of competition now in circulation.

The question of appointment of an Hon. Secretary was then brought forward, and it was pointed out that by the resignation of both the

President, Mr. Pocock, who had hitherto pasted the prints into the albums, and of the Hon. Treasurer, the duties of this office would be so much increased that no gentleman would be prepared to devote the necessary time for such a purpose. In the end it was unanimously resolved that Mr. W. M. Baylis be elected Hon. Secretary and Treasurer; and that a sum of three shillings per week be paid by the Society for assistance in the secretarial work and pasting prints into albums, &c., Mr. Baylis stating that he could obtain such assistance for that amount.

The vacancies in the committee, caused by the resignation of Messrs. Pocock, Senior, and Cowley, were filled up by the following gentlemen being elected in their stead:—Mr. Harris Heal and Mr. J. C. Cohen in place of Messrs. Pocock and Senier respectively, for London; and Dr. H. A. Roome, of Guildford, in place of Mr. F. Cowley, for the country.

Some discussion followed upon the present system of competitions, &c., and it was unanimously resolved that in future one album per month (at least) should be issued, and that there should be two prizes—one of ten shillings and one of five shillings—awarded by the members to the two best pictures in each, and that entrance fees for competitions should be abolished.

In order to stimulate the production of various classes of photography Mr. Bankart's suggestion was adopted, and it was decided that every alternate album should be composed of pictures of some one particular class, such as land and water subjects, interiors, architecture, portraiture, &c., and the dates and subjects of these special albums were decided upon for the ensuing year.

On the motion of Dr. Day, the Hon. Secretary was requested, on behalf of the members of the Society, to convey to Mr. Pocock their thanks for his services connected with the initiation of the Society, and to express the great obligation they were under to him for having discharged the unenviable duty of pasting some 1,400 prints into twenty-four albums; and also their great regret that his connection with the Society was about to terminate, this step being imperative in consequence of increasing business engagements.

After some general conversation, the meeting was dissolved.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The second outdoor meeting for the present season of the Manchester Photographic Society took place, under the leadership of Mr. Coote, on Saturday, the 14th inst., in the form of an excursion to a district which has on more than one occasion previously proved a delightful hunting ground, namely, Siddington, Marton, and Gawsworth.

The party, which included four ladies, left London-road station by the one o'clock p.m. train, and, on arrival at Macclesfield, were met by Mr. E. Woodward, who had bespoken wagonnettes for the drive, which covered a distance of some twelve miles.

Leaving photography out of the question, the weather was all that could be wished for as a typical summer day; but the object of the journey being of a purely photographic nature, it is to be regretted that the stiff and continuous breeze which prevailed throughout the afternoon rendered the work of the camera—at least in such a district—almost futile.

The first serious attempts at exposures were made at the famous "Marton oak," referred to in a previous account of a visit to the locality; but not a momentary lull was perceptible in the violent motion of the branches, during which the most rapidly-efficient exposure could have been made. This was the more disappointing as the freshness and beauty of its foliage were, probably, never seen in greater perfection; the ladies were, however, posed in the hollow of the trunk, which is one of considerable capacity, and several plates were "shied" on the group so arranged. After some further exposures on the rustic cottages which here abound, with their characteristic patches of flower garden, Marton Hall was visited. The building is one of the numerous half-timbered structures of the Elizabethan period which are met with in many parts of East Cheshire and Lancashire, and is by no means a bad subject for the camera. Unfortunately on this occasion the sun had got behind the subject, and it required considerable skill to shield its rays from the lens without cutting off a portion of the sky. Several plates were, however, successfully exposed.

The journey was then continued to Gawsworth, where it was hoped, by reason of its more sheltered situation, the high wind which had hitherto been so troublesome would no longer prove an inconvenience; but on arrival there the hope was soon found to have been a delusive one. The foliage of the splendid avenue of lime trees which forms the western approach to the church was found to be sufficiently unsteady to make photographic work difficult, and the two beautiful ponds in front of the church were so rippled with the breeze that the charming reflections which, under more favourable conditions, form so attractive a feature were only momentarily recognisable.

A detachment of the party paid a visit to the grave of Samuel Johnson, which is situated in a plantation skirting the Macclesfield road, and only a short distance from the church. The place is vulgarly called "Maggotty Johnson's grave." The eccentric individual who chose this "sylvan spot," for his last resting-place, is described under the *alias* of "Lord Flame" as a poet, wit, and player, and is supposed to have been a *protégé* of the Harrington family, lords of the manor, about the middle of the last century. The ladies were much interested in conning over the curious epitaph, and were afterwards photographed in a group at the head of the tombstone.

At the hostelry, whilst tea was being prepared, Mr. Garnet showed some very beautiful prints of instantaneous and other subjects. He also exhibited and described a very simple contrivance by which he was enabled to take four dissimilar subjects on one plate. The arrangement consisted of a sheet of vulcanite the size of the plate used, with a corner one-fourth of its superficial area cut away. This is inserted in a rebate made for the purpose inside the camera, and immediately in front of the sensitive plate. The cut-out portion of the vulcanite permits only one quarter of the plate to be exposed at one time, and by a sliding arrangement at the front of the camera the lens can be centered for each of the four quarters of the plate, which may be exposed in succession by simply changing the position of the vulcanite in front of the plate. The arrangement was much commended both for its simplicity and usefulness.

The next outdoor meeting will take place at Miller's Dale, on Saturday, the 21st instant; train from Central Station, Manchester, at one p.m. Members intending to join were requested to facilitate arrangements by giving in their names not later than Thursday, the 19th instant.

HALIFAX PHOTOGRAPHIC CLUB.

The usual monthly meeting of the Club was held on Tuesday, the 10th inst.,—Mr. T. Birtwhistle in the chair.

Mr. Councillor John Smith gave a practical demonstration of the Stannotype process of Messrs. Woodbury, Treadaway and Co. The great simplicity of all its working details, and the beauty of results, at once commanded the admiration of all present, the unanimous verdict being that a great future lay before the process.

A vote of thanks was passed to Mr. Smith for his very exhaustive lecture and elaborate preparations.

The thanks of the Society were heartily accorded to the patentees for the kind manner in which they had responded to Mr. Smith's invitation to send samples illustrating the mode of working their process.

The meeting was then adjourned.

ST. HELENS ASSOCIATION FOR THE PURSUIT OF SCIENCE, LITERATURE, AND ART.

Photographic Section.

A meeting of this Section was held on Wednesday, the 28th ult.,—Mr Heather in the chair.

It was stated that the Association had held its first field day at Knowsley Park on May 11. The members, favoured by fine weather, were busy all afternoon taking views of the hall, grounds, &c., with cameras ranging in size from $7\frac{1}{2} \times 5$ up to 12×10. A large number of prints and negatives of these views were shown at the meeting and much admired.

Mr. Brook exhibited a number of mounted prints of woodland scenery at Upholland taken with his 12×10 "instantograph," which were very pretty, but each had a light spot about two inches in diameter in the centre, which somewhat marred the picture.

Mr. Taylor exhibited a transparency, $7\frac{1}{2} \times 5$, of an exceedingly pretty rose-coloured tone, which he attributed to a finely-divided deposit of silver—an opinion shared by most members present. He intended trying to get the same tone again, and, if possible, to reduce it to a method of working, as it would be a very effective tone for lantern slides of autumn scenery.

Mr. Brook asked for information as to the best method of packing plates for safe carriage after exposing, as he intended taking a trip to Canada and the United States this summer, and did not intend developing until he arrived home.

A variety of plans were suggested, but all appeared to have some defect, taking up too much room, rubbing, &c. (Will any reader kindly oblige by giving a few hints on a plan he has tried?)

Mr. Sherlock forwarded the following communication on a *Process for Photographic Printing in Colours*:—

In this process it is necessary to use *coloured negatives*—that is, ordinary negatives which have been hand-painted in their proper tints with transparent colours.—1. Take a piece of ordinary sensitised paper and wash it to remove any free silver nitrate.—2. Place the washed paper in a solution of protochloride of tin, and expose to weak light until the silver chloride is reduced to sub-chloride, and the paper assumes a uniform grey colour.—3. Float the paper in a mixed solution of chromate of potash and sulphate of copper, and dry in the dark.—The paper is now sensitive to all the colours of the spectrum, and by printing on it with a coloured negative the colours of the negative will be reproduced. After printing wash with cold water and dry.

A discussion then took place on the process, but was adjourned until the members had tried it.

We learn that at the previous meeting of this Association, held on the 31st April,

Mr. Sherlock distributed a number of plates of his own manufacture to members present to try them. They were made by the aid of a naked spirit lamp, a salt of strontium having been dissolved in the spirit. His method of manufacture was original to the members of the Section. Mr. Sherlock dispenses with washing, dries quickly, and brushes the crystals of nitrate of potassium off when dry. He promised to demonstrate his method shortly. The plates were very good and rapid.

BERLIN ASSOCIATION FOR THE CULTIVATION OF PHOTOGRAPHY.

The annual general meeting of this Association was held on the 4th April,—Professor H. W. Vogel in the chair.

Herr Tonndorff, of St. Louis, U.S.A., forwarded a number of postage-stamp portraits with perforated edges and gummed on the back.

Herr Mandel, New York, sent some specimens of a dusting-on process, which the Chairman thought seemed to be identically the same, or at least very like, Captain Pizzighelli's process.

Herr Grimm, of Offenburg, presented a copy of a work entitled *An Atlas of the Hair of Human Beings and of Animals*, by Professor Waldeyer, profusely illustrated by photomicrographs.

Herr Gaillard showed a specimen sheet of his new autotypes.

The Chairman laid on the table a splendid album, bound in red velvet, containing M. Schapiro's pictures illustrating the *Life of a Madman*, with accompanying text by Gogol, in Prussian and French. He (the Chairman) also exhibited a new specimen of his process for photographing coloured objects with their true values of tints. It was a picture in the Japanese style, with yellow, green, and blue birds, and rose-coloured and dark blue flowers upon a yellow ground. The contrast between a photograph taken of this arrangement upon ordinary portrait collodion and one upon the specially-stained collodion was very striking. In the former many of the blue parts seemed over-exposed and the yellow under-exposed. In the latter the light parts came out light and the dark parts dark, except the vermilion red, which had hardly acted sufficiently. The Chairman explained that this was only a first result, and that in it he had not yet perfectly succeeded in managing the red, as the substance he added to the collodion in order to absorb red had decomposed the silver bath. In the dry method he had, however, secured the required action in the red.

Herr Joop remarked that, in spite of this still-insufficient action in the red, the results were surprising. Others spoke in similar terms, and the whole assembly rose to their feet to cheer Professor Vogel.

The Chairman replied, thanking them for their words of encouragement to persevere with his experiments, and said that he had already published what he had done and the substances used to attain this end.

Herr Quidde remarked that what was wanted was perhaps not so much a list of the names of the substances used and a bare enumeration of principles perhaps already known, but a thoroughly-worked-out, systematised process.

The Treasurer (Herr Bergmann) then presented his accounts, and the Librarian (Herr Haberlandt) and the Custodian (Herr Halwas) of the sample and travelling collection, presented their respective reports.

The office-bearers were then elected for the ensuing year as follows:—*President:* Professor Vogel.—*Vice-President:* Dr. Kayser.—*Treasurer:* Herr Bergmann.—*Secretaries:* Herren Quidde and Schultz-Hencke.—*Committee:* Herren Graf, Haberlandt, Halwas, Joop, and Milster. Professor Vogel has presided over this Association for twenty-one years.

Correspondence.

A SODA DEVELOPER.

To the Editors.

Gentlemen,—In some very delicate photomicrographic work lately, by artificial light, a soda developer was used which furnished finer gradation under my hands than the usual pyro-citric acid and ammonia solution under the same conditions; hence it may, perhaps, prove useful to others, and in other ways. It is a modification of several formulæ, therefore nothing new is claimed.

The pyro. solution is made somewhat after Edwards's plan, thus:—

No. 1.

Pyro	32 grains.
Glycerine	1 drachm.
Alcohol	5 drachms.
Distilled water	2 ,,

No. 2.

Sodic sulphite (Hopkin and Williams') ... 480 grains, dissolved in ten ounces of hot water.

No. 3.

Crystallised washing soda	480 grains,
Potassic bromide	3 ,,

dissolved in ten ounces of hot water.

(Genlain's formula, which he recommended with dry pyro.) Each filtered when cold.

For use: pour water on the gelatino-bromide plate; then take (say) for a quarter-plate, half a drachm of No. 1 and two and a-half drachms of No. 2, with five drachms of water. Pour the water off the plate, and pour on the mixed solutions (1 and 2). Let it stand for a minute or more; then pour into the rinsed developing glass two and a-half drachms of No. 3. Pour off the mixed solution (1 and 2) into the glass and return to the tray.

The development is gradual if correctly exposed. If over-exposed, add about ten drops of an eight-grain bromide solution. Well wash before passing to the hypo., and do the same before passing to the alum and citric acid bath. Afterwards soak well.

The solutions, used thus, permit of easy modification. Trusting it may prove useful to others, with every apology for trespassing on the spare corner,—I am, yours, &c., R. L. Maddox, M.D.

P.S.—To distinguish easily, *by touch*, between two similar bottles in use in the dark room, place a rather thick india-rubber band round one.—R. L. M.

"ENGLISH MISSTATEMENTS ABOUT THE LANTERN IN THE UNITED STATES."

To the Editors.

Gentlemen,—Under the above heading is given, in what appears to be a private trade journal, published by a C. T. Milligan, of Philadelphia, some attempt at a reply to a letter by me published in your issue of February 15th. Previous to dealing with it let me, first of all, say that I have had letters of thanks from photographers in the United States for having, as stated by one writer, "struck a blow which may prove the breaking up of the lantern ring." Although I was not previously aware of the fact, it seems feasible enough that a "ring" may indeed have been formed there to keep up prices. This, however, is a matter with which I do not, and shall not, concern myself.

In my letter of the date before mentioned I specified certain prices that were charged in the United States for both English and American productions, contrasting such prices with those charged in England. The statements I make and the prices I quote are characterised by the writer of the chief article in the trade journal in question (and which adopts as its title the *Exhibitor*) as erroneous, but which "would have been true about eighteen years ago, when war prices prevailed." Let us see.

The Milligan *Exhibitor* says:—"Statuary with black backs are seventy-five cents each, and *have not been higher for ten years.*" It will be in the recollection of those interested that I said the American price was "a dollar and a-quarter, or five shillings and twopence-halfpenny each." Upon looking at the nicely-printed "Catalogue of magic lantern slides manufactured and for sale" by E. L. Wilson, of Philadelphia, a townsman and, as proclaimed by C. T. Milligan, a patron of the last-named individual—a catalogue bearing date 1880—I find at page 69 the announcement that *statuary* "with backgrounds touched out" are, per slide, \$1·25, a list of seventy-two being given on that page, forty more following on page 70, prefixed by "\$1 25 each."

In the preface to the catalogue to which I allude the compiler of the work refers to the fact that "our long connection with photographers all over the world secures to us unequalled facilities for knowing not only where the best subjects are to be had but *how to get them at the lowest prices.*" This, I believe, will effectually dispose of the reckless statement made by the writer as to the prices not having been higher than seventy-five cents for ten years. As I am quoting the prices of one with whom he proclaims his business connection, I think I am justified in assuming that he has the means of verifying such quotation now that his attention is directed to his erroneous statements.

I spoke of "comic slip slides of good quality, lantern conundrums," and subjects of a similar description, as selling for a dollar and a-quarter each. This I am told is incorrect, and that comic slip slides are \$7·50 per dozen, *and have not been more expensive for twelve years.* Having the catalogue already mentioned as published in 1880 now open before me, I turn it up, and what do I find? At page 64 I read—"comic movable slides, coloured, \$1·25 each." On page 63 "lantern conundrums"—which, as my expert readers well know, are the simplest and cheapest affairs conceivable as regards cost of manufacture—are quoted at \$1·25 each. The English price of the class last mentioned is about equal to the price just mentioned if the odd dollar be thrown off, and be it well understood I speak of retail, not wholesale, prices. In short, every sale price quoted by me, and to which exception is now taken, is more than verified by reference to the catalogue from which I am now quoting.

It follows, therefore, that the writer of the leading article in the C. T. Milligan trade pamphlet, the *Exhibitor*, is either quite ignorant of the prices which prevail in his own city and among his own business *confrères* or otherwise entertains a charming disregard for facts. He says:—"We do not know Mr. J. Traill Taylor;" but he speedily makes it apparent that he does know that person by the palpable sensation evinced at the exposure made of the vendor of the bogus Morton condensers, concerning which, in the interest of the writer of the article in question, I draw a veil.

Perceiving that he is about to send you an American lantern catalogue, which, he says, "is about four times as large" as any English catalogue that has found its way to the American side of the Atlantic, and knowing precisely the catalogue to which reference is made, I ask you, gentlemen, if the said catalogue would, if added to one of the larger English catalogues, make it sensibly larger?

I have referred to letters I had received from America from photographers who desire to see the lantern "ring" broken up. Permit me to here acknowledge one in particular addressed to "C. T. Milligan" (presumably for publication in his *Exhibitor* for the next quarter), a copy of which has been sent to me by the author, Mr. C. Ferris, Malone, New York. As this gentleman, although a stranger to me personally, is a reader of this Journal, I doubt not that he will excuse the liberty I take in giving extracts from his letter which show very clearly the comparative state of the trade in both countries. Addressing Mr. Milligan, he enters fully into the prices charged by him, and makes no secret as to his estimate of the quality of wares for which he has had to pay so high an amount. By quoting the prices from contemporary Philadelphia catalogues he shows how reckless are the statements made by the writer of the Milligan article. After some remarks complimentary to myself he addresses Mr. Milligan thus:—"The trouble with you is that Mr. Taylor treads on your toes a little too hard when he referred to the exorbitant prices charged for lanterns in this country. But in this he was not very wild either, for lanterns that are catalogued at \$45 in this country are catalogued at \$20 to \$22·40 in London, and they are both *identically the same thing.* I speak of what I know, for we have one of each in town. One was bought in Philadelphia at \$45, the other in London at \$21, and in consideration of the purchaser being a clergyman they put in a dozen of Valentine's Scotch views. I wish you could see these views. They make yours look pretty sickly when thrown on the screen together." No more need be added.—I am, yours, &c.,

Woodgreen, London, June 17, 1884. J. Traill Taylor.

[Having received from Mr. J. T. Taylor the various documents referred to in the foregoing letter, and having also received Mr. Milligan's price list and *Exhibitor*, we are in a position to attest the accuracy of the prices quoted by Mr. Taylor.—Eds.]

"ON ALBUMENISING PAPER."

To the Editors.

Gentlemen,—Brilliant prints of deep purple tone, as in the old days, could be as easily obtained now if photographers would (one and all) express their wishes for such a change; *but* they must be prepared to assist, as well as albumenisers.

Paper, as now prepared with weak salting solutions, requires only a weak silver sensitising bath, and the result of such a weak state of things is—weak prints (deep purple tones are out of the question); and last, but not least, the pictures are not so permanent.

Increase the salting solution, *using pure albumen only*, and float on a silver bath of seventy to eighty grains—then we shall see better prints, rich, deep tones, and permanency better secured.

As regards "ready sensitised paper," the above remarks apply just the same. The demand nowadays is for everything cheap. The supply comes to hand, the buyer complains, and the vendors cannot alter it (at the price). If everything must be had cheap the materials lack quality, and the consequence is that everyone suffers in the end.

It rests entirely with the public to ask for better goods, consenting to pay a better price; *then* the change will gradually come. The cheap and nasty will disappear, smiling faces and fuller pockets will be the one general and universal result; at least such is the humble opinion of—Yours, &c., W. H. Hunt.

Willesden, N.W., June 17, 1884.

JOURNALS OF PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—As one of the "country members" so touchingly alluded to in your leading article in last number, as well as in the character of one who takes a lively interest in the welfare of all that is photographic, I crave your permission to make a few remarks on photographic societies in general and on their system of reporting proceedings in particular.

Mr. H. B. Berkeley's remarks having been, as he avers, wrongly reported in the *Journal* of the Photographic Society of Great Britain, he (Mr. Berkeley) has certainly a grievance of some weight; but his suggested cure for his grievance would, in my opinion, constitute a very serious and lasting grievance on the photographic public in general. If Mr. Berkeley will excuse the remark, I would say that his letter to the editor of the Parent Society's *Journal* is not written in his usual clear style, and I had to read it repeatedly and carefully before I arrived—or thought I had arrived—at the writer's meaning.

So far as I can gather Mr. Berkeley's suggestion is two-fold:—First, that papers to be read at meetings of societies should be printed before the meeting; and, second, that the public periodicals should not be allowed to publish remarks until they are issued in the Society's *Journal*. Mr. Berkeley's first suggestion is so curious, so unexpected to me, that I don't know what to say to it, except that it seems to me impracticable and undesirable, because a speaker often, while speaking, introduces matter which has occurred to him, and very valuable matter, during the remarks of others preceding him or even during the progress of his own remarks. I fancy Mr. Berkeley's second suggestion—the muzzling for a time of the public press—has been mooted before; but I, for one, would deprecate such a law, and fight it with all my force.

You, gentlemen, and other photographic editors, have reporters at the meetings of all societies; and your reporters, trained to their business, give, soon after the meetings, an account, more or less accurate, of what passed at the meeting in question. Your account and that of your contemporary "opposition," circulate throughout the country, wherever photographers are, a day or two after the meeting. If your reports are "meagre and incorrect," the Parent Society's *Journal* coming some weeks later, but to members only, is welcome and advantageous; but if your reports, as I must say I have always found them, are fair, accurate, condensed reports of what was said and done, the Parent Society's *Journal*, dropping in casually after the affair is past and almost forgotten, is of little or no use to anybody except to the members of that Society who take neither of the public photographic periodicals, and how many are there in that position? I think I have put the matter fairly.

I suppose that if the authorities of the Photographic Society of Great Britain saw no use for the Society's *Journal* they would not publish it, especially when its cost amounts to so serious a sum as £100 per annum, as is stated by one of your correspondents. The Edinburgh Photographic Society also sends out printed *Transactions*; but what the cost is I am not able to say. I confess myself that I cannot see why so large a sum as £100—or even £10—should be annually spent on what is, at the most, little more than a reprint of what appeared a month before in the public press. Greater accuracy might be expected, but from Mr. Berkeley's complaint is apparently not gained; while, as a rule, papers read are all the better for condensation. And why should not the editors of the weekly periodicals have access to the papers as soon as read, so that the public would *immediately* have accounts accurate and sufficiently detailed of all that was said and done at any particular meeting of any society?

And, once more: what is the reason we have not either at Pall Mall or at St. Andrew's-square shorthand writers? Surely that would be a "happy issue out of all our woes," and there would be no necessity for slips being sent out to some and not to others, as appears to be the system at present. Surely in the 500 members of the London, and the 600 of the Edinburgh, Societies there is one man who can write shorthand and would do so for a consideration. If there be not such a man the editors in the one case, and the secretary in the other, should be "told off for shorthand duty," or find a substitute.

In short, I think that the *Journal* of the Photographic Society of Great Britain should either appear immediately after the meetings, and in an accurate form, or else be discontinued, and the money now spent on it applied to some purpose conducive more directly to the good of photography and to the sustaining of the Society's character as the representative of British opinion and British work. I have always thought thus; but it is only now, when the pool is troubled, that I have ventured to dabble in it.—I am, yours, &c., Andrew Pringle.

Craigcleugh, N.B., June 16, 1884.

P.S.—My remarks do not apply so strongly to the Edinburgh Photographic Society, for there are many members not in a position to take a weekly journal; but any one paying one guinea a year subscription to the Photographic Society of Great Britain must take more than a passing interest in photography, and be a man beyond the necessity for petty economy.—A. P.

To the Editors.

Gentlemen,—With reference to the suggestion, made by Mr. Herbert B. Berkeley, that the weekly journals should wait for the "full and corrected" reports of the meetings of the Photographic Society of Great Britain published in the Society's own *Journal*, allow me to state that I have on more that one occasion been so misrepresented in these "corrected" reports, owing to an alteration of what had been said by a previous speaker, that if the circulation of the Society's *Journal* had not now sunk to such a low ebb I should have felt bound to try to set myself right with its readers.

On one occasion I was made to say that the "ferrous oxalate is not a modern developer." I certainly never either thought or said so. Nevertheless, I do not think that the plan of sending slips of their own remarks to individual members to correct is a good one, or one that ought to be tolerated, although in the instance mentioned, if I had been one of the favoured ones, I could have corrected the mistake referred to. A speaker may, by "correcting" his remarks, make those of other speakers appear pointless and absurd. By the putting into one sentence the observations of a speaker made before and after my remarks I have been represented as asking a question that had just been answered. The report should be that of what has taken place, and not of what each speaker would like to have said if he had had the benefit of hearing what subsequent speakers had to say.

I might have brought up the matter in question at one of the meetings of the Society, but that I was officially informed that such a subject would only be allowed to be entered into at the annual meeting. When it is considered that the annual meeting consists chiefly of the officers of the Society, who occupy the evening in mutually congratulating and in passing votes of thanks to each other, it will be understood what sort of reception anything in the nature of a complaint is likely to meet with at such a gathering.—I am, yours, &c., W. E. Debenham.

June 17, 1884.

Notes and Queries.

"How can I polish a small spot in the centre of my ground glass, as described by you, for purposes of accurate focussing? I may say that I have succeeded in obtaining a microscope which is well suited for the purpose.—E. P. H."——In reply: Try the effect of cementing a short piece of brass tube as a guide-piece upon the centre of the ground glass, and then working inside of this with a flat plate of brass or glass attached to a suitable handle, employing at first fine washed flour emery and then putty powder and water. Previous to applying this last-named powder let the glass or metal rubber be faced with pitch. In this way a fine surface will be obtained, which will be confined within the space bounded by the guide-piece, and not only act well, but look well. This, at any-rate, is our experience.

"I am extremely desirous of obtaining a powder which will give an instantaneous flash of the greatest possible actinic power—one by the light of which I can take a negative of an object in motion. Can you give me a receipt for making such a powder?—S. T. Brown."——In reply: Several years ago the best ingredients and proportions of a pyrotechnic powder for actinic illumination were carefully worked out by repeated experiments, and the following formula was the consequence of such investigation:—

Chlorate of potash (dried and powdered)........	4 ounces.
Sulphide of antimony..........	2 ,,
Sublimed sulphur..	1 ounce.
Magnesium filings..	1 ,,

Let these be carefully incorporated by mixing with a bone paper-knife. This powder flashes rapidly, giving an intensely luminous flame having a slightly violet tinge.

"I have taken several architectural photographs during the past few months, but the firm for whom I took them complain that they are faulty in consequence of the perspective being too sudden. They characterise them as 'distorted.' Now as I have read somewhere in the pages of The British Journal of Photography that, by adopting a certain process of recopying, the distortion in a photograph can be cured, I respectfully apply to you for aid in this annoying case.—Zeta."——In reply: This is a matter the proper remedy for which consists in the retaking of the negatives. The "distortion" spoken of is not correctly designated by this term, inasmuch as the photographs are a truthful rendering of the subjects as seen from a certain standpoint. The mistake lies in "Zeta" having selected the point of view too near the buildings, thereby producing a violent perspective; and, as we have said, nothing remains but to take them over again from a more distant point of view. From a portion of "Zeta's" letter which we have not given we find that he is inclined to attribute the fault to the employment of lenses of too wide an angle; but in this surmise he is mistaken. Had a narrow-angle lens been used the only difference in the result would be that from the standpoint taken the whole of the edifice could not have been got in; but the portion that was delineated would have had precisely the same violence of perspective as that in connection with which the complaint was made. It is quite true we have said that a distorted photograph could be cured by recopying, and we have on a previous occasion described the manner of doing so; but the distortion to which we then alluded was that of curvilinearity—not of perspective. If an architectural photograph be taken with a single lens the sides of the building will, if near the margin of the plate, be curved instead of being absolutely straight. The repairing of this by copying it with a lens arranged to give distortion of an opposite character, and to the proper extent, is a matter involving no difficulty; but to remedy an imperfection in perspective is impossible.

GEO. A. KEITH inquires if a microscopic objective, sufficiently powerful for photographing the general run of objects, cannot be made by mounting three or four short focus stereoscopic single lenses together.——In reply: Such a combination will answer exceedingly well for the larger class of objects, such as flies, fleas, and minute flowers, and we have known many excellent photomicrographs obtained by such agency. But a combination of this class will not be suitable for high-power objects, such as diatoms; for these a properly-constructed microscopic lens of short focus will be necessary.

J. CHAMBERLAIN writes:—"Can you give me a little advice with regard to the following questions, for which I shall feel very much obliged, being quite a novice? I have a vignette of a friend who is deceased, and it is the only one there is of him. How can I copy it? Ought it to be copied on to a gelatine dry-plate first? I tried in my printing-frame with some paper, and you can tell the result: it was what you would call a positive on paper. What exposure should I give, and can I take a copy by gas-light? What is the cause of the stains on the photograph enclosed? They come red in the toning bath, or, in fact, do not tone at all. I sometimes fancy that it is in connection with the paper, which is procured ready sensitised. What is the cheapest enlarging apparatus in existence, and could an ordinary view lens be used for the purpose?"——In reply: To copy the vignette proceed as follows:—Place it in front of the camera under such circumstances as to enable a beam of direct sunlight to be reflected upon it from a mirror, which may be held in the hand during the operation. If the copy is to be the same size as the original it will be necessary to expand the camera to double the focus of the lens, which with the camera you are using can scarcely, we imagine, be done unless your lens is of short focus. With a very small stop and a gelatine plate give an exposure of from six to ten seconds, and develope by a tentative system; that is to say, let the strength of the ammonia be such as to cause the development to proceed very slowly, thus allowing plenty of time for the addition of either bromide, pyro., or ammonia as required. For such copying a landscape lens will answer the purpose quite well. The stain on the print enclosed appears to be the result of contact with a minute portion of hyposulphite of soda. The cheapest form of enlarging camera is that constructed on the principle shown at page 221 of our ALMANAC for 1884; but a portrait lens should be employed.

Exchange Column.

I will exchange a four-wheel dark carriage (can also be used as a wagonette) for a 10 × 8 landscape camera with double dark slides.—Address, B. C. D., Athenæum, Bristol.

I will exchange a carved cabinet, with five changes, for anything useful in photography; a good 10 × 8 camera preferred.—Address, GEORGE READ, photographer, Market-place, Preston.

I will exchange a new mahogany sliding-body camera, fitted up with half-plate lens, for a good violin and case.—Address, JAMES ALSTON, 80, Kemp-street, Fleetwood, Lancashire.

I will exchange a whole-plate camera, half-plate ditto, and a quarter-plate ditto, for a 5 × 4 rapid rectilinear, by Dallmeyer, or backgrounds.—Address, BINDON, photographer, Egham, Surrey.

I will exchange a whole-plate lens, by Charles Chevalier, and a cabinet lens, by Ed. Burton. Wanted, grass and fur rugs, or any good studio accessories.—Address, F. V., Southwark Park-road, S.E.

I will exchange a thorough good cabinet lens, by a good maker, for a good Victoria camera and lenses; also several books on chemistry in exchange for anything useful in photography.—Address, S. HYAMS, Guernsey.

I will exchange a good revolving walnut stereoscope, by Dallmeyer, for a large-size binocular field glass, external condition no object if optical arrangements are all right; also Robinson's *Picture Making* and *About Photography and Photographers*, for *Monckhoven's Traité Pratique de Photographie au Charbon*.—Address, HARMER, Wick, Littlehampton.

I will exchange a good whole-plate camera, mahogany, double swing-back, bellows-body (for studio use), with extra back for 10 × 8, two cabinets on a plate, and three dark slides, a good half-plate lens (portrait) by Lerebours, and a lens for 18 × 15 landscapes, by Grubb, for a good English lever or Albert chain; a lot of photographic things also.—Address, Mrs. KUFFAM, 11, Victoria-grove, Kensington, W.

Answers to Correspondents.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHS REGISTERED.—

E. Debenham, 79, Princes-street, Edinburgh.—*Four Photographs of Sir Stafford Northcote.*

ALF. WERNU.—Any camera-maker would, doubtless, supply what you require.

E. WATSON.—Yes; by doing what you propose you should obtain a studio with sufficient light for all practical purposes.

G. T. MUIR.—The subject of your letter is in no way connected with photography, but applies to a topic with which we cannot deal.

W. COX.—The way the so-called "magic photographs" are prepared is this:—After the print is taken from the frame it is washed to free it from silver; it is now immersed in a solution of bichloride of mercury until the image entirely disappears, and then well washed and dried. Now, if the paper be immersed in a solution of hyposulphite of soda the image will again make its appearance in a brown colour.

S. A. J.—Your pictures certainly bear out all that has been said on the subject. We are not aware that it has been denied that good portraits can be taken in an ordinary room.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—We regret that, owing to the lateness of the hour at which we received the report of the last meeting, we are obliged to postpone its publication till next week.

G. E. M.—Blood albumen can be procured from most drysalters. It is a regular article of commerce. As you only require it in small quantities, it will answer your purpose much better, we imagine, to purchase it than to make it for yourself.

F. J. DEAKIN.—Either of the lenses named will take a good portrait, but one will work in much less time than the other by reason of its larger aperture. With regard to the quality of the work produced by each there is little to choose.

G. J. LOOSMORE.—Any work on photography published twenty-five years or so ago will give you practical working details of the daguerreotype process. Possibly if you were to advertise you would be able to procure all the necessary apparatus.

LEEDS.—Some samples of bitumen answer much better than others. That which you have, and of which you enclose a sample, is certainly not suitable for photographic purposes. It appears to be a compounded article. You must procure a sample of the natural product.

SYNTAX.—Your fixing bath appears to have contained little or no hyposulphite of soda, as the prints darken immediately they are exposed to the light. If you prepare the solution, as you say, "five ounces to the pint," it is clear that you did not use hyposulphite of soda at all, but some other salt; hence the cause of your difficulties.

INITIATED.—All the portraits show a decided preponderance of top light. With the circumscribed space at your command we fear that you can scarcely make your back yard available for good portraiture. If you can erect a studio at such a height upon the wall as will enable you to obtain your light from the north it would be your best method of procedure.

A. J. SYMONDS.—The sample of pyroxyline is quite unsuitable for collodion emulsion, and, indeed, for any photographic purpose whatever. It has evidently been prepared for blasting purposes. The best way for you to dispose of the large quantity you have is to pull it into small tufts, place them in the open air, and fire them separately with a taper.

C. H. B.—We think it very probable that you are over-toning your prints. Try the effect of less toning, and the addition of a drop or two of nitric acid to the sensitising bath—just sufficient to give it an acid reaction to test paper. We believe that those who teach that kind of colouring supply their pupils with a pamphlet on the subject, but we are not positive on the point.

W. D. W.—The unpleasant appearance in the picture is caused by its being taken with a lens of much too short a focus; hence the angle included is abnormally large. If you take the view again from the same standpoint, using this time a lens of longer focus, you will have a much more pleasing result, as the angle included will be less; also, those unsightly buildings at the side will not then be in the picture—a still further improvement.

H. HILL.—If you re-read the reply given you will find that it was in reference to *enlarging direct* on canvas—quite a different thing to printing upon it from a negative. You are in error in saying that the permanence of the basis is of no consequence because the picture has to be painted over. As a matter of fact, if your silver basis fades the fading will make itself manifest through the paint. It is not a fact, as you assume, that oil-painted portraits of necessity crack and peel off. They do not, except the photograph be very carelessly produced.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next monthly technical meeting of this Society will be held on Tuesday next, the 24th instant, at eight o'clock p.m., in the Gallery, 5A, Pall Mall East.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—We are requested by Mr. F. A. Bridge, the Hon. Secretary and Treasurer of the above Society, to announce that, in future, all communications should be sent to his *new* address—East Lodge, Dalston-lane, London, E.

PHOTOGRAPHIC CLUB.—At the forthcoming meeting of this Club, at Anderton's Hotel, Fleet-street, on Wednesday next, the 25th inst., the subject for discussion will be the adjourned discussion—*On Printing-in Skies.* The Saturday afternoon outing will be held at North End and West Heath, Hampstead. Meeting afterwards at 6.30 at the "Bull and Bush."

POITEVIN MEMORIAL FUND.—We have received a cheque for two guineas from James C. Cox, Esq., Lochee, Dundee, towards this fund, and we commend to our readers the excellent remarks which accompanies Mr. Cox's contribution:—"To few men does photography owe more than to Poitevin, although a mere amateur. I cannot but add my mite in gratitude to one who has taught us so much."

JOURNAL OF PHOTOGRAPHY.

No. 1260. Vol. XXXI.—JUNE 27, 1884.

DRYING GELATINE PLATES IN HOT WEATHER.

In speaking of the drying of gelatine plates we refer principally to the performance of that operation during the process of preparation, as the after-drying of the negatives under no circumstances presents any difficulties.

Hot weather, it might be supposed, would be the most favourable for (at least) drying the plates, even though it does introduce difficulties in the matter of the setting of the gelatine. Once set, the process of desiccation might be expected to go on rapidly and regularly without giving any further trouble or anxiety How far this is from being the case most of those who have experienced the pleasures of plate-coating in summer weather will be aware; but, perhaps, some few may not suspect that the very means adopted to guard against the evil, and the precautions taken to promote rapid and equal drying, may frequently be the actual causes of the trouble.

On two or three occasions lately, during the fitful visits of sultry summer weather with which we are so familiar, our attention has been called to examples of the results of sudden attacks of irregular and abnormal drying. In each case the drying appliances have been of the most perfect description in use amongst amateurs. (We may here interpolate the remark that it is the amateur who suffers most in this way, for reasons which will be pointed out.) In two instances drying-boxes fitted with a gas arrangement for setting up an induced current of unwarmed air in an ascending direction were used, a third being on Mr. W. K. Burton's principle, in which the current of air moves in the contrary direction. All these have been in use for some time under precisely the same local conditions without giving the slightest trouble until the recent hot weather. Indeed, in one case the apparatus is provided with an arrangement by which the current of entering air can be heated to any desired temperature; and during the winter months it has been the practice to employ a temperature some degrees higher than that which has caused the recent troubles. But of this more anon.

A few words may be said of the effects produced in the instances which have come under our notice. These consist mainly of uneven drying marks following two—sometimes three—edges of the plate. At times the mark takes the form of a broad, irregular band along one edge only of the glass; but in all cases one portion of the plate presents a matt surface, and the other more or less glass. In two instances, however, the defect took a different form—the film refusing altogether to dry, reaching a sort of gummy stage beyond which it would not go without the application of a considerable degree of heat.
